RESUMO

Com o aumento do tempo de vida da população humana muitas modalidades médicas, incluindo a dermatologia, deparam-se com uma revolução na forma de garantir saúde e qualidade de vida aos pacientes. Em contato com o ambiente externo, a pele representa um órgão no qual as mudanças com o envelhecimento causam danos funcionais, além de potencial impacto estético e psicossocial. A epiderme, camada mais externa da pele, constitui uma barreira seletiva com destacada capacidade de renovação e manutenção da homeostasia corporal. Entretanto, o entendimento de diversos mecanismos associados à fisiologia e envelhecimento da epiderme permanece como desafio para a comunidade científica. Com base nesse cenário, o objetivo do presente trabalho foi compreender o atual estado da arte no tema de envelhecimento da epiderme e realizar experimentos voltados para lacunas existentes, com foco na integração de aspectos clínicos, fisiológicos, morfológicos, celulares e moleculares. O capítulo de abertura descreve uma avaliação global de transcritos associados ao envelhecimento da epiderme humana, com a técnica de microarranjos de DNA e coleta não invasiva com fitas adesivas. O estudo indica características moleculares específicas do fotoenvelhecimento epidermal, com alterações relevantes e complementares a dados clínicos e morfológicos prévios, como modulação das vias de organização do citoesqueleto de actina e sinalização de cálcio, expressão gênica alterada de proteínas do envelope córneo, e avaliação de um painel segmentado por décadas de vida que sugere aspectos inéditos de regulação homeostática da epiderme, além de genes com modulação contínua ao longo das idades. O segundo capítulo compara o envelhecimento nas regiões folicular e interfolicular da epiderme. Como um sistema biológico de simples obtenção e fácil manuseio, os bulbos dos folículos pilosos representam uma fonte rica de material epidermal distinto, conforme evidencias na ampla modulação gênica diferenciada. O terceiro capítulo inclui uma avaliação in vitro do envelhecimento da epiderme, com gueratinócitos de indivíduos de diferentes idades cultivados em monocamada e no modelo de pele equivalente. Os

vii

resultados evidenciam diferenças na expressão de marcadores moleculares de proliferação e diferenciação entre queratinócitos neonatais e adultos, mas não entre adultos de diferentes idades. Não houve diferença nas populações de células tronco, entretanto, observou-se aumento de células na fase proliferativa do ciclo celular em neonatos, assim como predominância de células na fase estacionária do ciclo celular em adultos mais velhos. Concluindo, os resultados obtidos no presente trabalho contribuem de forma significativa para o avanço do entendimento dos mecanismos moleculares afetados pelo avanço da idade da epiderme, possilitando a busca de novas alternativas no tratamento do envelhecimento cutâneo.

ABSTRACT

With the increase in lifetime of the human population many medical disciplines, including dermatology, are facing a revolution in the approaches to ensure healthcare and quality of life for patients. In contact with the external environment, the skin is an organ in which the changes of aging cause functional damage, in addition to potential aesthetic and psychosocial impact. Epidermis, the outermost skin layer, is a selective barrier with outstanding capacity for renewal and maintenance of the body homeostasis. However, the understanding of several mechanisms associated with skin physiology and aging remains a challenge for the scientific community. Considering this scenario, the objective of this work was to evaluate the state of the art knowledge on epidermal aging and to conduct experimental approaches to cover gaps that still exist on that theme, focusing on the integration of clinical, physiological, morphological, cellular and molecular aspects of epidermis aging. The opening chapter describes a study based on global transcriptional evaluation associated with aging of the human epidermis, using DNA microarrays and noninvasive tape stripping. This study reveals molecular characteristics specific of epidermal photoaging, with relevant findings complementary to previous clinical and morphological data, such as modulation of the actin cytoskeleton and calcium signaling pathways; altered gene expression of proteins of the cornified envelope; and evaluation of a segmented panel structured by decades of life, which suggests new aspects of homeostatic regulation in the epidermis and unvails genes with continuous modulation throughout different ages. The second chapter compares the gene expression patterns of the follicular and interfollicular regions of epidermis undergoing aging. As a biological system easily sampled and handled, the bulbs of plucked hair follicles represent a rich source of distinct epidermal material, as evidenced by the wide differential gene modulation that was detected. The third chapter includes an experimental in vitro evaluation of skin aging using keratinocytes isolated from individuals of different ages and cultured in monolayer and in skin equivalent models. Differences in the expression of proliferation and differentiation molecular markers between neonatal and adult

ix

keratinocytes were observed. No differences were found regarding the stem cell populations, however, neonates showed an increased percentage of cells in the proliferative phase of cell cycle, while older adults presented a predominance of cells in the stationary phase of cell cycle. The results herein presented provide novel insights on the molecular mechanisms affected by epidermal aging, enabling the search of new alternatives in the treatment of aging skin.

Dedico este trabalho a todos que são apaixonados pelo que fazem, porque procuram e conseguem fazê-lo sempre melhor!

"Knowledge in youth is wisdom in age." (Old proverb)

AGRADECIMENTOS

Agradeço a todos que contribuíram para o desenvolvimento deste trabalho, direta ou indiretamente, e que me ajudaram a atingir este objetivo de vida (profissional e pessoal) tão desejado!

Em especial...

À minha esposa, Raquel, que sempre me acompanha com amor, carinho, paciência e compreensão, nas novas trilhas que se abrem em nosso caminho.

À minha família: minha mãe Valdete, meu pai Elói, minha irmã Eloísa e meus sobrinhos Lucas e Danilo, que representam um porto seguro e sempre me apoiaram na construção dos alicerces que me sustentam até hoje.

À minha família adotiva: Heloisa, Artur, Rebeca, Edgar e Alice, pelo apoio de sempre, oficializado a partir de 2013, pelas brincadeiras e pelo carinho.

Ao Dr. Nilson Ivo Tonin Zanchin por ter acreditado em mim durante todo este tempo (até mais que eu mesmo em alguns momentos), por todo o apoio, parceria, compreensão, força, orientação, ensinamentos, paciência e pela oportunidade única que me ofereceu para alcançar este próximo nível.

Ao Dr. Howard Maibach, que me recebeu tão bem em seu laboratório no Departamento de Dermatologia da University of California San Francisco, e com quem tive a honra de aprender muito, estabelecendo uma parceria e compartilhando algumas publicações científicas contidas nesta tese e fora dela.

Ao time do Laboratório de Biologia Molecular do Grupo Boticário, onde desenvolvi este trabalho e tantos outros, por ser uma equipe que me dá orgulho: Carla (por todo suporte e parceria), Alessandro (por toda dedicação e apoio),

xvii

Camila e Bruna (pela ajuda nos trabalhos), Rodrigo, Desirée, Marcela, Talita, Ana, Carina, Andressa, Ariane, Sarah e todos que passaram algum tempo conosco.

Aos demais colegas do Grupo Boticário, pela convivência agradável dentro e fora da empresa e, em especial, ao Gustavo Dieamant, que contribui na elaboração de um dos artigos desta tese.

Aos meus gestores no Grupo Boticário, que me deram suporte e autonomia na execução do projeto: Israel Feferman, Richard Schwarzer e Giuseppe Musella.

Ao Frank Hollander e à equipe do American Journal Experts, pelas revisões de inglês, e ao André Antunes, pelo suporte com análises imunohistoquímicas.

Aos meus grandes amigos e familiares, distantes ou não, que sempre me ajudam em tudo, com frequência ou não, e em todas as situações, fáceis ou não.

À Olinda, pelos conselhos e apoio em momentos decisivos.

À Tita Reyes, que me recebeu com tanto carinho e atenção no laboratório do Dr. Howard Maibach, e também aos demais integrantes de sua equipe.

À Lourdes, secretária do Programa de Pós-Graduação em Genética e Biologia Molecular da UNICAMP, pelo suporte à distância.

Aos membros da banca por participarem da avaliação desse trabalho.

Ao Grupo Boticário pela excelente infraestrutura oferecida à pesquisa e pelo financiamento deste trabalho.

Ao Programa de Pós-Graduação em Genética e Biologia Molecular da UNICAMP.

1. INTRODUÇÃO

1.1. Conceituação do envelhecimento humano

A complexidade do envelhecimento humano pode ser analisada a partir de diferentes abordagens conceituais e teóricas. Segundo Santin (2010), a questão do envelhecimento se estende em todos os níveis das ciências humanas, das ciências econômicas, das ciências jurídicas e das políticas sociais. O termo envelhecimento conota movimento, remetendo a um processo de chegar à velhice, ou de se tornar velho. Em relação aos seres vivos, envelhecimento significa aproximar-se do fim da vida. De acordo com Del-Masso (2010), envelhecer é chegar pouco a pouco a um período mais avançado da vida ou perder a jovialidade e a beleza, além das possíveis perdas das habilidades cognitivas. É inquestionável que o processo de envelhecimento provoca no organismo modificações biológicas, psicológicas e sociais. Entretanto, é nas idades mais avançadas que esse processo torna-se mais evidente, o que faz com que a própria velhice seja mais notada do que o processo de envelhecimento. Por isso é mais fácil reconhecer o estágio final do envelhecimento, normalmente com base nas aparências físicas (Santin, 2010).

A constituição do envelhecimento humano, como um objeto distinto de estudo é relativamente recente, incluído como uma parte importante da gerontologia e da geriatria. A gerontologia não trata apenas do velho ou da velhice, ela inclui os fenômenos que levam à velhice. A geriatria, por sua vez, não trata apenas das doenças dos idosos, mas se preocupa, também, com as prevenções destas doenças (Santin, 2010). Do ponto de vista biológico, o envelhecimento é um processo complexo e contínuo que se caracteriza por alterações celulares e moleculares, com diminuição progressiva da capacidade de homeostase do organismo (Bagatin, 2008). Os fatores que interferem no envelhecimento podem ser intrínsecos (determinados pela constituição genética individual) e extrínsecos (exposições ambientais). Embora os mecanismos fundamentais envolvidos na patogênese do envelhecimento ainda necessitem de

mais estudos, uma massa crescente de evidências aponta para o fato de que múltiplas vias e vários elementos estão envolvidos no processo de envelhecimento celular e molecular (Makrantonaki e Zouboulis, 2007; Zouboulis e Makrantonaki, 2011). Sabe-se que o acúmulo de radicais livres e o estresse oxidativo que ocorre com a idade, contribuem para o fenótipo senil provocando alterações no organismo como desenvolvimento de tumores malignos, arteriosclerose, doenças neurodegenerativas e artrite reumatóide (Dröge, 2002). Outra causa descrita para o envelhecimento é o aumento da atividade inflamatória crônica, com o acúmulo de substâncias que desencadeiam uma série de danos teciduais (Caruso *et al.*, 2004).

No que se refere às descrições de processos moleculares associados ao envelhecimento, alguns mecanismos relacionados são: encurtamento e ruptura dos telômeros (Buckingham e Klingelhutz, 2011), perda de metilação no DNA com alteração na taxa de proliferação celular (Richardson, 2003; Bollati, 2009), acúmulo de mutações genéticas (como no gene de p53), alterações hormonais e alterações inflamatórias (Giacomoni, 2005). Johnson (2006) relata marcadores biológicos do envelhecimento que, mesmo na ausência de quadro patológico, representam indicativos da perda de capacidade funcional do organismo. O aumento de citocinas pró-inflamatórias (IL-1, IL-6 e TNF- α), diminuição da testosterona sérica, antioxidantes, alelos da apolipoproteína E, deleções no DNA e sinalizadores de resposta ao estresse são alguns exemplos destes marcadores.

1.2. Envelhecimento populacional

O tempo médio de sobrevida humana tem aumentado consideravelmente nas últimas décadas, sendo que os idosos passam a representar uma parcela significativa da população e o surgimento de indivíduos centenários não representa mais uma raridade (Farage *et al.*, 2010). De acordo com a Organização das Nações Unidas (ONU) (www.onu.org.br), uma transição única e irreversível do processo demográfico deve resultar em populações mais velhas em todos os lugares, sendo que a proporção de pessoas com 60 anos ou mais deve triplicar, e

o número de pessoas acima dos 80 anos deve quadruplicar na maior parte dos países até 2050. As estimativas do Fundo de População das Nações Unidas (UNFPA) (<u>www.unfpa.org.br</u>) também apontam que em 2050 80% das pessoas mais velhas do mundo viverão em países em desenvolvimento e a população com mais de 60 anos de idade será maior que a população com menos de 15.

No Brasil esta não é uma realidade distinta. O envelhecimento da população brasileira apresenta características de um processo acelerado, em ritmo significativamente maior se comparado com aquele já observado em diversos países europeus (Carvalho e Garcia, 2003). Com um perfil estável até os anos 60, o Brasil apresentava uma população jovem: 52% abaixo de 20 anos, e menos de 3% acima dos 65. A partir de então, um rápido e generalizado declínio da fecundidade foi o principal fator responsável pelo com estreitamento contínuo da base da pirâmide etária, que torna os grupos etários mais velhos proporcionalmente maiores em relação a toda a população (Carvalho e Garcia, 2003). Embora a menor fecundidade seja a principal responsável pelo envelhecimento populacional, o aumento da longevidade também contribui, de forma secundária, para esse fenômeno. Segundo dados publicados pelo Instituto Brasileiro de Geografia e Estatística (IBGE) em 29 de agosto de 2013 (www.ibge.gov.br/home/estatistica/populacao/projecao_da_populacao/2013/defaul t.shtm), a esperança de vida ao nascer, que em 2013 chegou a 71,3 anos para homens e 78,5 anos para mulheres, em 2060, deve atingir 78,0 e 84,4 anos, respectivamente, o que representa um ganho de 6,7 anos médios de vida para os homens e 5,9 anos para as mulheres.

Além de representar uma mudança significativa em termos socioeconômicos, o novo perfil populacional impacta na atuação de diversas modalidades médicas, visando promover a saúde e bem-estar de todos. Buscando alternativas multidisciplinares para combater o problema, profissionais de diferentes modalidades agrupam-se, como na Sociedade Brasileira para o Estudo do Envelhecimento (SOBRAE) (www.sobrae.com.br), que inclui dermatologistas, médicos esteticistas, do trabalho, do exercício e do esporte. De fato, os cuidados geriátricos tem se tornado uma questão de saúde mundial (Thapa *et al.*, 2012).

1.3. Dermatologia e o envelhecimento cutâneo

A dermatologia representa uma das áreas médicas mais impactadas pelo envelhecimento populacional, uma vez que o envelhecimento cutâneo pode causar danos funcionais, além de potencial impacto estético e psicossocial. A pele representa um sistema complexo e dinâmico, no qual alguns sinais do processo de envelhecimento natural são notados visivelmente.

Diversas doenças da pele associadas ao envelhecimento não representam condições letais, mas podem comprometer a qualidade de vida dos indivíduos afetados. As erupções pruriginosas crônicas, por exemplo, podem diminuir a autoestima, deixar o portador em situações constrangedoras, interferir no sono, e muitas vezes, provocar depressão, isolamento social e deterioração da aparência, além de representar uma condição desconfortável e, não menos importante, possuir elevado custo de tratamento. Outras características observadas na pele envelhecida são a capacidade reduzida de cicatrização, o enfraquecimento da imunidade local que aumenta o risco de infecções, uma maior lentidão na resposta a tratamentos e um aumento na predisposição a reações adversas (Farage *et al.*, 2010). De impacto mais drástico, a pele envelhecida apresenta maior disposição para o desenvolvimento de tumores, exigindo maiores cuidados principalmente quanto à exposição solar (Tsatsou *et al.*, 2012).

Com o envelhecimento da população mundial, a elevação da qualidade de vida e, portanto, o prolongamento do período ativo e produtivo dos indivíduos, a aparência da pele toma cada vez mais importância para garantir a segurança e confiança dos indivíduos no convívio social. Muitas vezes, a aceitação do envelhecimento humano não é uma das tarefas simples, já que os indivíduos costumam acreditar que só os outros envelhecem e que eles devem permanecer eternamente jovens ou maduros (Del-Masso, 2010). Dessa forma, a busca por tratamentos estéticos para reverter os sinais do envelhecimento cutâneo, como a formação de rugas ou o aparecimento de manchas, tem aumentado muito em consultórios dermatológicos ou mesmo no mercado cosmético (Wollina *et al.*, 2008). Entretanto, apesar das diversas opções terapêuticas disponíveis, muitas

delas carecem de legitimidade científica, levando ao questionamento sobre a real fundamentação da abordagem dermatológica anti-idade (Kreyden, 2005).

1.4. Funções, estrutura e tipos de pele

A pele é o maior órgão do corpo humano, representando 15% do peso total, e responsável por seu revestimento e proteção. Apesar de amplamente descrita, a estrutura básica da pele foi revisada no Anexo 1 devido à sua importância no tema central deste trabalho. Além disso, uma revisão detalhada abrangendo diversos aspectos anatômicos, histológicos e imunohistoquímicos da pele humana normal pode ser conferida no trabalho de Kanitakis (2002). Em decorrência de sua arquitetura e propriedades físicas, químicas e biológicas, a pele é responsável por diversas atividades, tais como proteção imunológica, termorregulação, percepção sensorial, secreção e proteção contra radiação solar (Mota, 2006).

A estrutura da pele é formada por duas camadas principais: epiderme e derme. Adjacente, encontra-se o tecido subcutâneo ou tecido adiposo, algumas vezes descrito na literatura como uma terceira camada cutânea (Figura 1).

Figura 1. Estrutura morfológica da pele, indicando suas camadas e os principais elementos presentes em cada uma delas.

A epiderme representa a porção mais externa da pele, formada por diversas camadas celulares justapostas e organizadas em uma estrutura multilamelar. Compondo uma verdadeira barreira seletiva, a epiderme controla as trocas de moléculas entre o interior do corpo e o ambiente externo. Majoritariamente formada por gueratinócitos (~85% das células totais), possui também melanócitos, células de Langerhans e células de Merkel. Por sofrer um constante processo de descamação, a epiderme precisa ser renovada continuamente (Milstone, 2004). A renovação inicia-se com a multiplicação de células proliferativas (epidermopoiese) na porção mais interna da epiderme, a camada basal, originando os queratinócitos que passam por um processo de diferenciação à medida que são empurrados para a superfície epidermal pela ocorrência de novas divisões celulares na camada basal, em um processo que leva em torno de quatro semanas para se completar (Figura 2) (Fuchs e Raghavan, 2002). A diferenciação dos queratinócitos é marcada por mudanças de cunho molecular, estrutural e funcional, dando origem a uma epiderme estratificada do interior à superfície corporal, composta por camada basal, camada espinhosa, camada granulosa e estrato córneo (Fuchs e Raghavan, 2002; Simpson et al., 2011). Em algumas áreas, como palmas das mãos e solas dos pés, é possível observar uma camada extra, conhecida como estrato lúcido, entre a camada granulosa e o estrato córneo (Brohem et al., 2011). No estrato córneo, os queratinócitos atingem seu ponto máximo de diferenciação, podendo ser chamados de corneócitos: células mortas, anucleadas e de morfologia achatada, que representam blocos de proteínas e lipídios, unidos entre si e mergulhados em uma matriz lipídica (Eckhart et al., 2013). Muito mais que um elemento de proteção mecânica, a epiderme representa um tecido metabolicamente ativo que passa periodicamente por ciclos de renovação completa, em constante equilíbrio dinâmico (Fuchs e Raghavan, 2002). Alguns autores consideram o funcionamento da epiderme como paradoxal, exibindo grande estabilidade para proteção do organismo contra agressões externas ao mesmo tempo em que mantém considerável flexibilidade de seus componentes celulares para garantir regeneração tecidual e capacidade de resposta a diferentes estímulos (Simpson et al., 2011). Devido a tal capacidade, a

epiderme representa um componente decisivo na manutenção da homeostasia corporal, com funções de: 1) barreira de proteção contra insultos mecânicos e químicos (Lulevich *et al.*, 2010; Kirschner *et al.*, 2013), 2) manutenção do equilíbrio hidro-iônico do organismo (Proksch *et al.*, 2008; Kirschner *et al.*, 2013), 3) defesa imunológica contra patógenos e eliminação de toxinas (Geusau *et al.*, 2001; Baroni *et al.*, 2012; Polak *et al.*, 2013), e 4) proteção contra radiação solar e atividade antioxidante (Shindo *et al.*, 1994; Yamaguchi *et al.*, 2006).

Figura 2. Esquema representativo do processo de renovação epidermal.

A derme representa a porção interna da pele, cuja estrutura é rica em elementos de matriz extracelular, como as fibras de colágeno e elastina, apresentando também vasos sanguíneos, vasos linfáticos e terminações nervosas. Basicamente, a derme é responsável por todo o tipo de sustentação da pele, em termos físicos e nutricionais, representando cerca de 90% da espessura cutânea. A derme apresenta espessura variável de acordo com a região do corpo observada, apresentando duas regiões distintas: a papilar (superficial, delgada e composta de tecido conjuntivo frouxo com fibras mais esparsas) e a reticular (mais

profunda, espessa e composta de tecido conjuntivo denso com estrutura fibrilar mais compactas). Os fribroblastos representam o principal tipo celular residente na derme, responsáveis pela síntese de diversos componentes da matriz extracelular, incluindo proteínas e outros elementos da substância fundamental amorfa (tais como fluido intersticial e complexos de glicosaminoglicanos e proteínas, denominados proteoglicanos e glicoproteínas). Além disso, a derme também apresenta células relacionadas à defesa imunológica, incluindo células dendríticas e diversos outros tipos celulares não permanentes que migram para derme a partir dos vasos sanguíneos em situações específicas como no caso das respostas inflamatórias (incluindo macrófagos e neutrófilos) (Farage *et al.*, 2010).

Para uma correta funcionalidade da pele, a comunicação entre suas duas principais camadas é essencial. Ao captar sinais do ambiente externo, a epiderme aciona mecanismos específicos, como no caso da produção de citocinas frente à radiação ultravioleta, que atingem a derme e estimulam uma resposta biológica. A ativação desta cascata de sinalizações intra e intercelulares, pode gerar estímulos em feedback para a epiderme, formando um ciclo de interações contínuas e regulação mútua entre as camadas (Brohem e Lorencini, 2014). Ainda, a derme com sua rica estruturação fibrosa e a presença de vasos sanguíneos, fornece constante suporte e garante o abastecimento de nutrientes para manutenção viável da epiderme. A manutenção do equilíbrio hidro-iônico é mais um exemplo funcional das interações entre epiderme e derme. As trocas de água entre os diferentes compartimentos da pele e o meio externo, dependem de três fatores: 1) umidade do meio externo, 2) capacidade de substituir a perda de água por evaporação (movimento de água de dentro para fora, a partir dos vasos sanguíneos) e 3) habilidade intrínseca do estrato córneo de impedir ou reduzir a perda de água transepidérmica (Bouwstra et al., 2008). Para que tudo isso ocorra, são estabelecidas redes de sinalizações complexas formadas entre os dois componentes celulares principais da pele: queratinócitos e fibroblastos. Essas interações têm se demonstrado fundamentais para inúmeros processos, tais como crescimento e diferenciação de células, reparação tecidual, cicatrização de feridas,

além do desenvolvimento e tratamento de diversas doenças (Brohem e Lorencini, 2014).

Complementando as atribuições funcionais da epiderme e derme, o tecido subcutâneo ou adiposo representa uma camada de células com elevada capacidade de armazenamento energético na forma de lipídeos, além de exercer papel de proteção mecânica e auxílio no controle da temperatura. Além das camadas, a pele também apresenta seus anexos, como as glândulas sudoríparas e os folículos pilossebáceos (unidades compostas pela associação de folículos pilosos e glândulas sebáceas) (Farage *et al.*, 2010).

A pele pode ser classificada em diferentes tipos com base em critérios como: 1) produção de sebo e hidratação ou 2) coloração. Considerando a produção de sebo e hidratação, a Sociedade Brasileira de Dermatologia (SBD) (www.sbd.org.br) define quatro tipos de pele:

• Normal, tipo de pele menos frequente com textura saudável e aveludada, elasticidade ideal e quantidade adequada de gordura natural, aspecto rosado, com poros pequenos e pouco visíveis, pouco propensa ao desenvolvimento de espinhas e manchas;

 Seca, caracterizada pela perda de água em excesso, normalmente com poros poucos visíveis, pouca luminosidade e mais propensa à descamação e vermelhidão, maior tendência ao aparecimento de pequenas rugas e fissuras, podendo ser causada por fatores genéticos e hormonais, assim como condições ambientais (tempo frio ou seco, vento, radiação ultravioleta ou até mesmo banhos demorados e com água quente);

 Oleosa, com aspecto mais brilhante, úmido e espesso por causa da produção de sebo maior do que o normal, poros dilatados e maior tendência à formação de acne, cravos e espinhas, podendo ser causada por fatores genéticos, alterações hormonais, excesso de sol, estresse e dieta rica em alimentos com alto teor de gordura;

• Mista, tipo de pele mais frequente, com aspecto oleoso e poros dilatados na "zona T" (testa, nariz e queixo) e seco nas bochechas e extremidades, tem

espessura mais fina, com tendência à descamação e ao surgimento de rugas finas e precoces.

A coloração da pele resulta de uma combinação de fatores como a espessura das camadas celulares e a quantidade de pigmentos, com destaque para a melanina produzida pelos melanócitos da epiderme. A quantidade de melanina sintetizada tem forte influência de componentes genéticos, mas também pode ser modulada por fatores como idade, ocorrência de resposta inflamatória, variações hormonais e influências ambientais como tabagismo, alcoolismo, poluição e exposição à radiação solar. Além disso, a produção de melanina pode ser regulada em diferentes estágios biomoleculares como o nível de atividade da tirosinase nos melanócitos (principal enzima envolvida na síntese de melanina), mudanças na rota biossintética (podendo originar pigmentos mais claros de feomelanina ou pigmentos mais escuros de eumelanina) e na transferência de pigmentos produzidos para os queratinócitos (Mota, 2006). Com base na coloração da pele e sua reação à exposição solar, a SBD adota a escala Fitzpatrick (Figura 3) para classificação dos fototipos cutâneos, criada em 1976 pelo dermatologista e diretor do departamento de Dermatologia da Escola de Medicina de Harvard: Thomas B. Fitzpatrick. Tal escala considera seis fototipos cutâneos, sendo eles:

• Fototipo I, com pele branca que sempre queima, nunca bronzeia e é muito sensível ao sol;

• Fototipo II, com pele branca que sempre queima, bronzeia muito pouco e é sensível ao sol;

• Fototipo III, com pele morena clara que queima (moderadamente), bronzeia (moderadamente) e tem sensibilidade normal ao sol;

• Fototipo IV, com pele morena moderada que queima (pouco), sempre bronzeia e tem sensibilidade normal ao sol;

• Fototipo V, com pele morena escura que queima (raramente), sempre bronzeia e é pouco sensível ao sol;

• Fototipo VI, com pele negra que nunca queima, totalmente pigmentada e é insensível ao sol.

Figura 3. Escala de Fitzpatrick para classificação dos seis fototipos cutâneos. Adaptado de www.laserdocs.co.uk.

1.5. Mudanças cutâneas com o envelhecimento

Por representar um órgão em contato direto com o ambiente externo, a pele está frequentemente exposta à ação de agentes agressores. Essa exposição ao longo do tempo pode refletir diretamente na velocidade de envelhecimento cutâneo, caracterizado pela formação de rugas e além de perda de resistência e elasticidade. Em pessoas com exposição constante à radiação solar, por exemplo, tais efeitos tendem a ser mais pronunciados ou acelerados (Scharffetter-Kochanek *et al.*, 2000). Waller e Maibach (2005 e 2006) fizeram um compilado das principais modificações que afetam a estrutura da pele com o avanço da idade, incluindo tendência de diminuição do fluxo sanguíneo, redução da espessura de derme e epiderme, alterações na organização das fibras colagênicas e elásticas, diminuição na atividade de enzimas que atuam em processos de modificação póstraducional, formação de agregados proteicos, modificações na deposição de glicosaminoglicanos que tendem a interagir menos com moléculas de água e mudanças no conteúdo lipídico.

Quanto aos aspectos clínicos, o envelhecimento da pele é caracterizado por atrofia tecidual e rugas finas, com comprometimento de fibras elásticas e surgimento de elastose na derme reticular. A exposição constante à radiação solar promove o aparecimento de sinais intensificados, ocorrendo formação de rugas mais profundas, espessamento da pele, amarelamento, ressecamento, surgimento de melanoses, telangiectasias, poiquilodermia, queratoses actínicas e aumento da probabilidade de ocorrência de câncer. Ainda, as rugas derivadas de efeito direto da ação excessiva da radiação solar podem corresponder a até 85% daquelas presentes na pele envelhecida (Bagatin, 2008). Intrinsicamente, ao longo dos anos, a pele também apresenta mudanças que podem ser observadas em suas diferentes camadas (Figura 4). Ocorrem alterações como redução de gordura no tecido subcutâneo, aumento de substância elastolítica na derme superior, destruição da estrutura fibrilar, aumento da quantidade de substância intercelular e infiltrado inflamatório moderado. Em um trabalho amplo, que avaliou 45 amostras de pele distintas de homens e mulheres com idades entre 17 e 81 anos, foi observado que, com o envelhecimento há uma diminuição na espessura e na quantidade de camadas de células viáveis na epiderme, aumento na quantidade de grânulos querato-hialinos, achatamento da junção dermo-epidermal, maior presença de material elastolítico na derme, aumento de infiltrado inflamatório com presença de trabéculas fibrosas mais espessas e atrofia da hipoderme. O envelhecimento cronológico também afeta o metabolismo de fibroblastos, reduzindo seu tempo de vida, capacidade de divisão celular e potencial de produção de colágeno. Ainda, durante o envelhecimento, o aumento da espessura das fibrilas de colágeno diminui a elasticidade da pele (Levakov et al., 2012).

Figura 4. Análise histológica do envelhecimento cutâneo, com destaque para características como redução da espessura epidermal, achatamento da junção dermo-epidermal e desestruturação de fibras na derme. (A) Pele jovem (indivíduo de aproximadamente 30 anos). (B) Pele envelhecida (indivíduo de aproximadamente 60 anos).

Trabalhos relacionados ao estudo de síndromes de envelhecimento precoce ou síndromes progeróides também têm contribuído com o entendimento da importância de alguns genes no avanço do envelhecimento cutâneo, como no caso das síndromes de Hutchinson-Gilford, Werner, Bloom, Cockayne etc. Estes estudos, particularmente no caso da síndrome de Hutchinson-Gilford, que representa a forma mais dramática de envelhecimento prematuro, têm apontado para processos chave no avanço do envelhecimento cutâneo, incluindo mecanismos de transcrição, replicação e reparo do DNA, instabilidade genômica, senescência celular, ciclo celular, apoptose, função mitocondrial, proteólise mediada por ubiquitina, matriz extracelular, síntese de lipídeos, metabolismo celular e diferenciação de células-tronco (Makrantonaki e Zouboulis, 2007; Capell *et al.*, 2009; Zouboulis e Makrantonaki, 2011).

Apesar das diversas descrições de efeitos do envelhecimento sobre a pele, a maioria dos trabalhos permanece focada na derme e na desorganização de sua estrutura rica em matriz extracelular (Luebberding *et al.*, 2012).

1.6. Mudanças funcionais e moleculares da epiderme com o envelhecimento

Há diversas mudanças que acometem a função de barreira da epiderme com o envelhecimento (Ramos-e-Silva *et al.*, 2012). Um estudo recente realizado com 150 mulheres entre 18 e 80 anos observou que, com o aumento da idade, há uma queda contínua na produção de sebo e diminuição no valor de pH, com significativo aumento detectado em mulheres de 50 a 60 anos, período típico da ocorrência de menopausa, mas sem mudanças na perda de água transepidermal ou no nível de hidratação do estrato córneo (Luebberding *et al.*, 2012). Alguns trabalhos apontam a redução da espessura da epiderme que surge com o envelhecimento como decorrente da diminuição da quantidade e/ou atividade de células tronco na camada basal ou na região dos folículos pilosos. Este tema é bastante discutido na comunidade científica e há concordância quanto ao fato de que a homeostase das células-tronco da epiderme pode mudar com o

envelhecimento, embora os mecanismos específicos relacionados a este processo ainda não sejam bem esclarecidos. No trabalho de Lock-Andersen et al. (1997) é evidenciado que a espessura do estrato córneo não varia entre grupos de jovens e idosos, mas há uma redução na chamada epiderme celular, formada pelos estratos que apresentam células viáveis. Outros trabalhos também apontam evidências de um aumento no número de células-tronco com a idade, embora descrevam a ocorrência, em paralelo, de um decréscimo na função e atividade metabólica das mesmas. Um estudo demonstrou que há um desequilíbrio na via de sinalização Jak-Stat e na produção de citocinas das células-tronco epidermais, de forma que o declínio em sua funcionalidade poderia ser compreendido como um mecanismo para a supressão de tumores que poderiam surgir com o avanço da idade (Doles et al., 2012). Outros trabalhos evidenciam o afinamento da epiderme com o avanço da idade associado à redução na capacidade proliferativa das células e ao aumento na taxa de apoptose, sendo este último mecanismo reforçado pela observação do aumento na expressão de Fas (Gilhar et al., 2004; El-Aal et al., 2012). Ainda, há observações demonstrando que, com a idade, não há alterações na atividade das células-tronco da epiderme, sendo que as mesmas mantêm suas características ao longo do envelhecimento cutâneo, diferentemente do que ocorre com as chamadas células amplificadoras transientes. Neste caso, o aumento da quantidade destas células pode ser interpretado como um mecanismo compensatório para a queda de sua atividade, buscando uma manutenção das funções da epiderme (Liang et al., 2004; Stern e Bickenbach, 2007; Charruyer et al., 2009).

Um estudo desenvolvido por Schmuth *et al.* (2005) demonstrou que existem diferenças na produção de proteínas transportadoras de ácidos graxos na epiderme quando comparados tecidos de origem embrionária e adulta, indicando uma regulação dinâmica destes constituintes ao longo do desenvolvimento. A atividade de esfingomielinase também é reduzida, sendo que indivíduos de 80 anos apresentam 25% da atividade encontrada em indivíduos de 20 anos, reforçando como o envelhecimento compromete o metabolismo de lipídeos na epiderme (Yamamura e Tezuka, 1990). Como um elemento essencial para a

diferenciação dos queratinócitos e manutenção da homeostase da barreira cutânea, a distribuição de cálcio entre as camadas da epiderme na face também parece variar com a idade. Na pele jovem e saudável, há um gradiente de cálcio caracterizado por uma baixa concentração nas camadas mais internas (camada basal e estrato espinhoso) com um aumento na disponibilidade extra e intracelular de cálcio que atinge um pico de maior concentração no estrato granuloso. Em amostras de pele de indivíduos mais velhos, entretanto, o cálcio apresenta-se distribuído igualmente entre todas as camadas da epiderme, sem a formação do gradiente observado na pele jovem, sugerindo uma disfunção em bombas ou canais iônicos que pode culminar com as alterações morfológicas tipicamente observadas com o avanço do envelhecimento cutâneo (Denda *et al.*, 2003).

Outros achados apontam para diferenças na eliminação de danos provocados por radiação na epiderme quando amostras de indivíduos de diferentes idades são comparadas. No estudo de Yamada et al. (2006) foi verificado por imunohistoquímica e immunoblotting que a remoção de dímeros de pirimidina induzidos por UVB acontece de forma mais lenta na epiderme de indivíduos mais velhos. No grupo de 22 a 26 anos, o tempo de remoção completa dos dímeros foi de 4 dias, frente a 14 dias no grupo de 70 a 78 anos. Os resultados indicaram que a idade é um fator mais importante que a dose de radiação para a remoção dos dímeros de pirimidina da epiderme. Além das modificações que acometem os queratinócitos, estudos também apontam para mudanças associadas ao envelhecimento que afetam outros tipos celulares presentes na epiderme, como uma redução no número de melanócitos (com redução de 10 a 20% a cada década depois dos 25-30 anos) e células de Langerhans, comprometendo as funções de proteção contra radiação ou imunológica da pele (Ortonne, 1990; Wulf et al., 2004). Assim como em outros tecidos ou outras doenças, os estudos baseados em biologia molecular e expressão dos genes ainda precisam ser mais bem explorados para explicar os fenômenos que acometem a epiderme ao longo do envelhecimento. Sabe-se, por exemplo, que o nível de detecção da filagrina por imunohistoquímica diminui em amostras de epiderme com idades mais avançadas. Entretanto, o nível de

expressão gênica da filagrina não parece ser afetado pela idade. Ainda, avaliando a disponibilidade de aminoácidos derivados da degradação enzimática da filagrina para a formação dos fatores naturais de hidratação (NMF), foi verificado que a quantidade total de aminoácidos no estrato córneo de indivíduos mais velhos foi maior que nos jovens, sugerindo que a redução na disponibilidade de filagrina preconizada pelo avanço da idade pode ser derivada de sua proteólise nas camadas superiores do estrato espinhoso e não de alterações referentes à diminuição na expressão gênica (Takahashi e Tezuka, 2004). Este exemplo ilustra bem a necessidade de se esclarecer mecanismos moleculares para a melhor compreensão e talvez até para o desenvolvimento de terapias específicas para o tratamento da epiderme.

1.7. Evolução contínua em biologia molecular impacta na dermatologia

Com a conclusão do Projeto Genoma Humano, novas perspectivas foram abertas para ajudar as gerações futuras a viver melhor e atingir idades superiores aos 100 anos com a dignidade almejada. Assim como nas outras áreas, a dermatologia também foi impactada pelos avanços científicos da revolução genética. Nos últimos anos o número de publicações científicas abordando o tema "expressão gênica" aplicado aos cuidados da pele aumentou consideravelmente. Além disso, a biologia molecular tem estado mais presente na abordagem do envelhecimento cutâneo, que, como um processo altamente complexo, envolve a ação simultânea e contínua de diversos fatores que desencadeiam uma diminuição progressiva da capacidade homeostática da pele. Considerando tudo isso associado à própria complexidade histológica da pele, os estudos nesta área vêm sendo muito favorecidos pela aplicação de tecnologias de avaliação global dos fenômenos biológicos. A utilização destas tecnologias deu origem ao termo "skinomics", referindo-se à avaliação global de moléculas biológicas associadas ao desenvolvimento e funcionalidade cutânea (Blumenberg, 2005).

Aliada ao avanço dos estudos da pele e suas alterações, a biologia molecular também oferece vantagens para o desenvolvimento de tratamentos

mais eficazes no combate ao envelhecimento cutâneo. A farmacogenômica representa uma nova área que surgiu a partir destes conceitos, envolvendo a aplicação de tecnologias como o sequenciamento de DNA, análise da expressão gênica e técnicas estatísticas em pesquisas e testes relacionados a fármacos ou ingredientes. Um dos princípios defendidos pela farmacogenômica é o desenvolvimento da chamada medicina personalizada, onde fármacos e suas combinações são otimizados em uma composição única para cada indivíduo (Squassina *et al.*, 2010). Esta nova perspectiva permite levar em consideração as variações individuais tanto na identificação das necessidades, como na escolha dos ativos e acompanhamento da resposta de um indivíduo ao tratamento escolhido na busca da máxima assertividade e eficácia. Mais uma vez, as tecnologias inovadoras derivadas da revolução genética têm favorecido ainda mais o avanço e detalhamento dos conceitos de farmacogenômica aplicados à dermatologia (Rizzo e Maibach, 2012).

1.8. Justificativa e estrutura do trabalho

De fato, as mudanças nas propriedades físicas de diversos tecidos do corpo humano com o avanço da idade vêm sendo descritas há algumas décadas. Muitos trabalhos já avaliaram as mudanças que acometem a organização da matriz extracelular dérmica, associando a perda da integridade da pele a tais fenômenos. A importância destes estudos é indiscutível uma vez que a perda da configuração estrutural original da matriz extracelular pode ter impactos diretos na função dérmica (Bailey, 2001). De acordo com Cristofalo e Pignolo (1996), embora alterações na natureza dos contatos de células senescentes sejam normalmente atribuídas a mudanças na composição da matriz extracelular, ainda permanecem dúvidas quanto à produção de proteínas específicas não relacionadas à matriz ou de moléculas associadas à membrana. Paralelo a isso, diversas dúvidas permanecem com relação às mudanças provocadas pelo envelhecimento que podem afetar os queratinócitos na epiderme. Poucos trabalhos têm sido desenvolvidos no que se refere especificamente à avaliação dos efeitos do

envelhecimento na epiderme, mesmo em termos de avaliação de sinais clínicos da função de barreira (Luebberding et al., 2012). Tendo em vista a falta de conhecimento científico específico sobre o envelhecimento da epiderme humana, alguns estudos começam a surgir focados em biologia molecular, embora não focados na compreensão global dos mecanismos associados ao envelhecimento da epiderme e, geralmente, baseados em ensaios de cultivo celular in vitro (Gilchrest et al., 1994; Baek et al., 2003; Brégégère et al., 2003; Perera et al., 2006). Gromov et al. (2003) desenvolveram um trabalho bastante interessante e complementar o que está sendo proposto na abordagem deste estudo, porém com análise global de proteínas associadas ao envelhecimento da epiderme. Além de seus achados interessantes, os autores concordam quanto às limitações encontradas na literatura atual para mecanismos moleculares associados ao envelhecimento cutâneo: a maioria dos estudos globais está concentrada em análises de fibroblastos, a complexidade do tecido cutâneo dificulta a interpretação de estudos globais (como os já realizados para tecido muscular, cerebral e hepático) e muitas vezes há utilização de modelos animais com baixa reprodutibilidade para tecido correspondente humano.

O entendimento dos mecanismos moleculares de envelhecimento cutâneo pode abrir novas estratégias para o tratamento de diversas doenças que surgem com o avanço da idade, incluindo câncer (Makrantonaki e Zouboulis, 2007), além de auxiliar na busca de tratamentos estéticos intensamente procurados nas clínicas dermatológicas atualmente, como no caso da eliminação de rugas sem a necessidade de procedimentos cirúrgicos ou altamente invasivos. Apesar da maioria dos estudos apontar para a derme e a composição de sua matriz extracelular como o principal componente na determinação do envelhecimento cutâneo, uma redução na hidratação do estrato córneo da epiderme pode contribuir com a formação de rugas de 25 a 85% maiores (Flynn e Mccormack, 2010). Além disso, uma grande parte das doenças que acometem a pele estão associadas a células específicas da epiderme, como no caso dos melanomas. Estas características fazem da epiderme um alvo rico para novos estudos
moleculares de espectro global, visando elucidar aspectos ainda pouco explorados sobre a biologia desta camada cutânea.

O presente trabalho contém três capítulos no formato de artigos científicos elaborados no tema de envelhecimento epidermal. O primeiro capítulo descreve uma avaliação global de transcritos modulados de acordo com o envelhecimento da epiderme humana, utilizando a técnica de microarranjos de DNA e coleta não invasiva da epiderme com fitas adesivas. O segundo capítulo contém uma comparação dos estudos realizados sobre o envelhecimento nas regiões folicular e interfolicular da epiderme. O terceiro capítulo inclui uma avaliação *in vitro* do envelhecimento da epiderme, com queratinócitos de indivíduos de diferentes idades cultivados em monocamada e no modelo de pele equivalente. Nos documentos anexos, são apresentados também dois trabalhos de revisão da literatura, um deles representando uma análise aprofundada e abrangente, descrevendo os recentes avanços em biologia celular e molecular com modelos tradicionais da função e envelhecimento da epiderme. O outro trabalho apresenta uma revisão de ordem prática no tema, contemplando as alternativas terapêuticas possíveis para tratamento do envelhecimento epidermal.

2. OBJETIVOS

2.1. Objetivo geral

Realizar avaliação global de transcritos da epiderme humana utilizando a técnica de microarranjo de DNA, e buscando identificar marcadores moleculares, vias metabólicas ou agrupamentos gênicos diferencialmente expressos com o avanço da idade.

2.2. Objetivos específicos

• A partir de coletas de amostras de epiderme humana de mulheres de diferentes faixas etárias, avaliar a expressão gênica associada ao envelhecimento utilizando microarranjos de DNA;

 Identificar os principais conjuntos de genes diferencialmente expressos, associados a processos biológicos ou a vias metabólicas moduladas pelo envelhecimento da epiderme;

• Realizar análise comparativa da expressão gênica com o envelhecimento da epiderme obtida por técnicas distintas de coleta: fita adesiva e pelos de sobrancelha;

• Estabelecer modelos experimentais *in vitro* com o cultivo de células epidermais para avaliar o efeito da idade do doador.

3. EXPERIMENTOS E RESULTADOS

3.1. Capítulo I (Artigo experimental I)

Title: Transcriptome of in vivo human epidermal aging in sun-exposed skin

Running title: Transcriptome of human epidermal aging

Abstract

Skin is a complex system formed by the dermis and epidermis, which both comprise a variety of cell types. As the outer layer of skin, the epidermis forms a barrier on the surface of the body to protect against external aggressions and maintain its balance of fluids and ions. In addition to the action of external factors, the skin undergoes the intrinsic aging process, which governs the entire body of an organism. Single-target and large-scale studies have been used extensively to try to understand the mechanisms that underlie the skin damage caused by intrinsic and extrinsic factors. Nevertheless, most molecular processes remain to be understood. In this study, we assessed human epidermal aging in sun-exposed skin using non-invasive tape stripping and DNA microarrays analysis for ~20,000 genes. To better understand the mechanisms of aging as a continuous and gradual process, traditional young versus old analysis was complemented by different strategies to evaluate a broad panel of volunteers from each decade of life between 20 and 80 years old, representing an unprecedented approach for epidermal aging evaluation. By adopting a minimal fold change (FC) value of 1.5 and a p-value cut-off of 0.05, statistically significant differences were observed for 3,247 distinct human genes, with 4,146 up-regulated and 717 down-regulated. Although the number of up-regulated genes was higher than down-regulated genes, 63 gene ontology (GO) terms were associated with down-regulation, and only 24 were associated with up-regulation. Down-regulated genes were predominant at FC 3.0 with a 0.05 p-value cut-off, indicating that in terms of significant biological process enrichment and the intensity of FC expression, downregulation is a critical condition for epidermal aging of sun-exposed skin. Relevant pathways comprising differentially expressed genes (DEGs) include the actin cytoskeleton (37 DEGs) and calcium signaling pathways (31 DEGs). Clustering analysis was performed using more stringent criteria (FC: 2.0, p-value cut-off: 0.01) to separate the young (20-40 years) and old groups (50-80 years). However, this clustering did not order the groups in a continuous and crescent sequence of ages, and the old group showed clear segregation into two distinct blocks, indicating that age-associated changes should not be interpreted as part of a linear process.

Analysis of specific gene expression profiles associated with each decade evidenced a dynamic and oscillating pattern of epidermal transcription with aging. A cluster with a single member, the SPRR2G gene, showed continuous increased expression, and a cluster with 20 members showed continuous reduced expression throughout a lifetime. In conclusion, the data presented in this article contribute to the understanding of the dramatic molecular changes that the epidermis experiences during aging.

Introduction

Skinomics represents a set of global biological techniques that are applied to skin studies, such as genomics, transcriptomics, proteomics, and metabolomics (Blumenberg, 2005). Because of its accessibility, skin was one of the first targets analyzed by DNA microarrays, and dermatology embraced this approach early (Blumemberg, 2012 and 2013). Currently, several investigative strategies have been used to understand the molecular networks modulating skin function, covering aspects of health and disease and the occurrence of multifactorial processes such as aging (Robinson et al., 2009; Villaseñor-Park and Ortega-Loayza, 2013). However, considering the inherent complexity of skin and the limitations of whole-tissue analysis, e.g., that it is not able to localize messenger RNAs to specific cell types, reducing the variables used in an experimental design may sometimes be recommended instead of extrapolating generalized conclusions (Mitsui et al., 2012). The epidermis and dermis are distinct skin layers in terms of their function, cellular and molecular composition, and even embryonic origin. This biological heterogeneity challenges the correct interpretation of skinomics because global analysis reflects a mixture of signaling pathways and molecular responses that occur simultaneously in different biological compartments. To avoid such complexity problems, some groups have worked with isolated skin layers or cells to achieve comprehensive results without traces of confounding material (Jansen and Schalkwijk, 2003; Mitsui et al., 2012).

If skin biology studies have significant sophistication per se, the elucidation of skin aging-related mechanisms adds several pieces to this intricate research puzzle (Jansen and Schalkwijk, 2003). As a highly complex biological process involving cumulative deterioration, aging impairs homeostasis over a lifetime in different tissues and organs (Kirkwood, 2005). Although the impact of age on cutaneous functionality and organization has been extensively studied, little is known about the aging of the human epidermis, despite its essential role as the main functional barrier of the body where the symptoms of aging can be visually perceived with significant aesthetic and psychosocial implications (Farage *et al.*,

2010; Sotoodian and Maibach, 2012). In fact, some "omics"-oriented studies have addressed the aspects of aging that affect the most abundant epidermal cell type, keratinocytes, by applying experimental *in vitro* models (Baek *et al.*, 2003; Darbro *et al.*, 2005; Perera *et al.*, 2006; Sprenger *et al.*, 2010). However, it is important to remember the differences between cultured cells and their *in vivo* counterparts. Cultured keratinocytes are less differentiated than those *in vivo*, and some points must be considered when comparing the cell biological mechanisms of *in vitro* senescence with those taking place in *in vivo* aging (Hwang *et al.*, 2009; Mitsui *et al.*, 2012). In addition, the dynamics of *in vivo* skin aging can be even more complex if the simultaneous influence of intrinsic factors (physiological components and genetic predisposition) and extrinsic factors (external insults, particularly from solar radiation) is considered (EI-Domyati *et al.*, 2002; Farage *et al.*, 2008). Therefore, representative *in vivo* studies of epidermal aging are lacking, particularly those that employ "omics" approaches and include intrinsic and extrinsic age-related components.

In this study, we assessed the *in vivo* transcriptome of human epidermal aging in sun-exposed skin using non-invasive tape stripping and DNA microarrays analysis for ~20,000 genes. To better understand the mechanisms of aging as a continuous and gradual process, traditional young versus old analysis was complemented by different strategies to evaluate a broad panel of volunteers from each decade of life between 20 and 80 years old. This study represents an unprecedented approach for epidermal aging evaluation.

Materials and methods

Volunteers and samples

The Research Ethics Committee institutional review board from Universidade Positivo, Curitiba, Brazil, approved this study, and written informed consent was obtained before enrolling volunteers for participation in this study, which was performed in compliance with the Declaration of Helsinki Principles.

Epidermal samples were obtained using Q-Squames Skin Sampling Discs (CuDerm, Dallas, TX, USA) applied to the back of the left or right hand (random choice) of women of different ages and skin phototype II or III according to the Fitzpatrick scale. Twenty-five adhesive tapes were collected from the same area of each volunteer; the first five were discarded, and the remaining 20 were stored in RNAlater solution (Ambion, Austin, TX, USA). Samples from 62 healthy women were used for microarray analysis (Table S1), and an independent panel of 20 healthy women was used for real-time qPCR validation (Table S3).

RNA extraction and processing

RNA extraction was performed using the RNeasy Mini Kit (Qiagen, Hilden, Germany). Tape strips, two at a time, were agitated in Tissuelyser LT (Qiagen) for 5 minutes at 50 Hz with lysis buffer and two 7-mm magnetic beads (Qiagen). The procedure was repeated until all 20 tape strips from each volunteer were processed, followed by the subsequent steps for total RNA extraction. Purified RNAs were quantified with a 2000c NanoDrop spectrometer (Thermo Scientific, Wilmington, NC, USA), and the quality was checked using a 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA, USA) and a Agilent RNA 6000 Pico Kit (Agilent Technologies). Because of the low total RNA yields, the samples were amplified with the Arcturus RiboAmp PLUS HS Kit (Applied Biosystems, Carlsbad, CA, USA) and SuperScript III Reverse Transcriptase (Applied Biosystems). All procedures were performed according to manufacturers' instructions.

RNA labeling, hybridization and microarray scanning

Amplified RNAs were processed using the Turbo Arcturus Labelling Kit (Applied Biosystems), and samples were labeled with Cy5. Universal Human Reference RNA (Agilent Technologies) from a unique batch was labeled with Cy3 for use in the data normalization of different arrays (Novoradovskaya *et al.*, 2004). The use of exogenous RNA from the Agilent RNA Spike-in Kit (Agilent

Technologies) was also used for the further calibration of the microarray measurements (Yang, 2006). After fragmentation with the Gene Expression Hybridization Kit (Agilent Technologies), 1:1 ratio mixtures of Cy5-labeled RNA from each volunteer and Cy3-labeled Universal Human Reference RNA (Agilent Technologies) were co-hybridized to two-color Agilent Whole Human Genome Oligo 44K microarrays (Agilent Technologies) to evaluate ~44,000 probe sets, which target 19,596 genes. Scanning and image analysis were performed using the Agilent DNA Microarray Scanner (Agilent Technologies). All procedures were performed according to manufacturers' instructions.

cDNA synthesis and real-time qPCR

To validate the gene expression patterns in the RNA samples, cDNA was obtained using a ReverAid First Strand cDNA Synthesis Kit (Thermo Scientific). cDNA from three or four volunteers in the same age group was pooled in equal quantities, resulting in three samples for analysis for each group (young and old), and real-time qPCR was performed in duplicate for each sample using the ViiA 7 Real Time PCR System (Applied Biosystems) with the TagMan Fast Advanced Master Mix (Applied Biosystems) and TaqMan Gene Expression Assays (Applied Biosystems) for the following target genes: beta actin (ACTB, Hs99999903 m1); CCAAT/enhancer binding protein, alpha (CEBPA, Hs00269972 s1); fibroblast growth factor 5 (FGF5, Hs03676587 s1); forkhead box Q1 (FOXQ1, Hs00536425 s1); frizzled-related protein (FRZB, Hs00173503 m1); growth arrestspecific 7 (GAS7, Hs00932959 m1); melanoma antigen family A, 10 (MAGEA10, Hs00253298 s1); olfactory receptor, family 11, subfamily G, member 2 (OR11G2, Hs02340403 s1); olfactory receptor, family 4, subfamily F, member 4 (OR4F4, Hs03406040_gH); and olfactory receptor, family 7, subfamily D, member 2 (OR7D2, Hs01089409 s1). Glyceraldehyde-3-phosphate dehydrogenase (GAPDH, Hs03929097 g1) was used as an endogenous control. All procedures were performed according to manufacturers' instructions.

Data analysis

Microarray raw data were extracted using the Agilent Feature Extraction v8.1 software (Agilent Technologies, Santa Clara, CA, USA). Data visualization and analysis were performed using the GeneSpring v12.5 software (Agilent Technologies). Data normalization was performed within and across the arrays using per gene, per chip normalization, according to Agilent's recommendation. To detect the differentially expressed genes (DEGs) between experimental conditions, the following analyses were performed: 1) unpaired t-test with a corrected p-value (Benjamini Hochberg FDR) and a cut-off of 0.05 for young versus old comparisons; 2) unpaired t-test with a corrected p-value (Benjamini Hochberg FDR) and a cut-off of 0.01 for segmentation according to different decades of life (each group compared to the immediately preceding younger group); and 3) one-way ANOVA with post-hoc Tukey's HSD with a corrected p-value (Benjamini Hochberg FDR) and a cut-off of 0.01 for continuous gene expression analysis throughout aging (all groups compared to the youngest condition, i.e., ~20 years old). Hierarchical clustering was performed using the Euclidean distance metric and Ward's linkage rule. K-means clustering analysis was used for DEGs identified when all groups were compared to the youngest condition (~20 years old). The minimal FC, pvalues and specific statistical tests were defined according to each analysis. For real-time gPCR experiments, the FC was calculated using the ddCt technique (Livak and Schmittgen, 2001). The DAVID database was used to conduct functional enrichment analysis (Huang et al., 2009a and 2009b). The human genome was used as a reference, and regulated GO terms were ranked according to their p-values (or called EASE score, a modified Fisher's exact test) with a cutoff of 0.01; Benjamini correction was also considered for ranking but not elimination (www.david.abcc.ncifcrf.gov). The KEGG database was used for the analysis of modulated pathways (Kanehisa and Goto, 2000; Kanehisa et al., 2014), considering the human genome as a reference and an adjusted p-value cut-off of 0.01 (www.genome.jp/kegg). Network connectivity was analyzed using STRING

v9.1 (Franceschini *et al.*, 2013), a database of known and predicted protein interactions (<u>www.string-db.org</u>).

Results

Panel of volunteers and sample considerations

To cover a broad spectrum of the aging process, we recruited a panel of volunteers comprising 62 women who were distributed according to different decades of age i.e., 20 ± 1 years old (12 volunteers), 30 ± 1 years old (9 volunteers), 40 ± 1 years old (9 volunteers), 50 ± 1 years old (9 volunteers), 60 ± 1 years old (8 volunteers), 70 ± 1 years old (8 volunteers) and 80 ± 1 years old (7 volunteers) (Table S1). Using non-invasive adhesive tape stripping, our analysis focused on the outer viable layers of epidermis, including the granular (mainly) and spinous layers. Most of the stratum corneum was discarded with the first five tapes collected because its dead cell components are not suitable for RNA extraction. The basal layer was likely not accessible due to its deeper position. Thus, epidermal differentiation and keratinocyte activity/structure are that biological processes that are most likely to be revealed by this approach. Moreover, tapes were collected from sun-exposed areas, providing samples with particular clinical and morphological interests with regards to epidermal aging.

Young versus old epidermis microarray analysis and technical validation using real-time qPCR

To establish comparisons with previous skin aging studies, young versus old analyses were initially performed by dividing the volunteers into two groups: 20-40 years old (30 volunteers) and 50-80 years old (32 volunteers) (Table S1). By adopting a minimal fold change (FC) value of 1.5 and a p-value cut-off of 0.05, statistically significant differences were observed for 4,863 probe sets (3,416 recognized HGNC mapped probe sets representing 3,247 distinct human genes),

with 4,146 up-regulated and 717 down-regulated (Table S2). Technical validation of the microarray results was performed using real-time qPCR in an independent young versus old panel including 10 volunteers who were 25 ± 3 years old and 10 volunteers who were 55 ± 4 years old (Table S3). Similar results were found for the expression of 10 randomly selected genes (up-, down- or non-regulated) (Figure 1).

Figure 1. Real-time qPCR validation of microarray results. These qPCR results represent the median (± SD) of triplicate analyses using an independent secondary panel of volunteers (10 young, 10 old). GAPDH was used as an endogenous control. A complete list of regulated genes can be found in Table S2.

Separate lists of the up- and down-regulated genes (Table S2) were analyzed in the DAVID database to identify significantly up- and down-modulated biological processes, respectively, ranked according to p-value (cut-off 0.01) (Table 1). Although the number of up-regulated genes was higher than that of downregulated genes, the opposite trend was found for biological processes, i.e., 63 gene ontology (GO) terms were associated with down-regulated gene expression, and 24 were associated with up-regulated gene expression. Filtering data with distinct FC values of 1.5, 2.0 and 3.0 and maintaining the p-value cut-off of 0.05 demonstrated that the ratio between the up- and down-regulated genes decreased with an increase in FC criteria (Table S4). Notably, the down-regulated genes were predominant in the 3.0 FC dataset. Therefore, one may conclude that despite the higher number of up-regulated genes in terms of significant biological processes enrichment and FC expression intensity, the down-regulation of gene expression is critical for the epidermal aging of sun-exposed skin.

1. DEGs, differentially expressed genes.

To identify the modulated pathways, the complete list of modulated genes was analyzed using the KEGG database (Table S2). Forty pathways showed significant modulation and were ranked according to their p-values (cut-off: 0.01) (Table S5). In addition to statistical significance, biological interpretation is essential for meaningful pathway analysis. Of the identified pathways, ~50% were associated with human diseases and organismal systems not necessarily related to skin. Other pathways could be linked to key aspects of epidermal aging, such as focal adhesion, cytokine-cytokine receptor interaction, Wnt signaling pathway, MAPK signaling pathway, cell adhesion molecules, Jak-STAT signaling pathway and Hedgehog signaling pathway, which helps explain the clinical, morphological and/or functional alterations of aged epidermis. The actin cytoskeleton pathway has 37 DEGs in common with our results, and 32 of these genes are up-regulated, which corresponds to significant ACTB up-regulation according to the microarray and gPCR techniques and might help explain the clinical observations of solar keratosis in sun-exposed skin (Figure 2a). The calcium signaling pathway has 31 DEGs in common with our results, which likely contribute to the impaired calcium gradient observed in aged epidermises (Figure 2b).

Comparison to previous studies

To verify the alignment of our findings with key previous aging-related studies, specific comparisons were established. A recent transcriptome analysis of intrinsic epidermal aging reported only 75 DEGs between five young and five old donors (18-24 and 70-75 years old, respectively) (Raddatz *et al.*, 2013). Despite the noted biological and technical variations and population specificities, 15 common DEGs were shared by our studies (Table S6), including cross-linked envelope proteins in keratinocytes, adhesion molecules and components of signal transduction pathways.

Figure 2. Biological pathways modulated by sun-exposed epidermal aging from the KEGG database. (A) Actin cytoskeleton pathway. (B) Calcium signaling pathway. A complete list of regulated genes can be found in Table S2. White boxes represent species independent genes from the reference pathway map that were not differentially expressed in our study; green boxes represent human genes from the pathway that were not differentially expressed in our study; blue and red boxes represent human genes from the pathway that were respectively up- or down-regulated in our study. Graphic representations: _____ gene product; O other molecules (mostly chemical compounds); _____ another map; _____ activation; _____ inhibition; ---> indirect effect; ----> indirect link to another map; +p phosphorylation; -p dephosphorylation.

With a representative sample size for better analyzing intergroup changes despite intragroup variability, an elegant study was performed by Glass et al. (2013) as part of the MuTHER (Multiple Tissue Human Expression Resource) project. Using a linear mixed model and a large panel of 856 female twins ranging in age from 39 to 85 years old, 1,672 probe sets were differentially expressed in photo-protected skin throughout a lifetime, of which 273 were also detected in our analysis (Table S7). Yan et al. (2013) conducted a skin photoaging evaluation with paired analysis of sun-exposed and sun-protected samples from 21 Chinese women ranging from 34-55 years old. A total of 1,621 modulated probe sets were identified, and 250 also present in our data (Table S8). If considered together, the Glass et al. (2013) and Yan et al. (2013) studies had 42 DEGs in common with our results, including significant epidermal markers such as keratins and keratin associated proteins. To determine broader aging aspects, we checked whether known aging-related genes from Human Ageing Genomic Resources (HAGR) were present in our dataset (de Magalhães et al., 2009; Tacutu et al., 2013). GenAge is a database within HAGR that consists of 298 genes potentially associated with human aging, and 43 of these genes are correlated with our study (Table S9), including markers of actin filament organization, regulation of cell growth and progression through the cell cycle as well as genes related to protein modification and apoptosis. The two lists of ~40 shared DEGs, which were obtained from the comparison of our results with those of Glass and Yan or the HAGR data, were evaluated using the DAVID and STRING databases and revealed distinct profiles (Figure 3), which are detailed in the discussion section.

Figure 3. Associations between modulated biomarkers of sun-exposed epidermal aging. Analyses were performed with differentially expressed genes (DEGs) by comparing our dataset with other studies. (A) DEGs in common with Glass *et al.* (2013) and Yan *et al.* (2013), sun-protected and sun-exposed skin aging studies, respectively, showing genes mainly related to tissue-specific biological processes and only one association. (B) DEGs in common with Human Ageing Genomic Resources (HAGR), a study of aging not restricted to skin, showing genes related to broad biological processes and many molecular associations. Complete lists of genes are found in Tables S7-S9. Different node colors are used only as a visual aid. Big nodes indicate proteins with available structural information. Stronger associations are represented by thicker lines.

Epidermal aging transcriptome segmentation according to different decades of life

As previously stated, our panel of volunteers whose DNA was used for microarray analysis comprised women distributed across different age decades. Because the number of volunteers per experimental group was significantly reduced by panel segmentation, more restrictive criteria were adopted for the selection of DEGs, i.e., considering a minimal FC of 2.0 and a p-value cut-off of 0.01. Clustering analysis was performed to evaluate the consistency of traditional grouping, i.e., young versus old, in reflecting the evolution of epidermal aging (Figure 4a). Indeed, the young (20-40 years) and old groups (50-80 years) were separated, but at least two specific observations are notable from the analysis. First, clustering did not order the groups into a continuous and crescent sequence of ages, indicating that the age-associated changes should not be interpreted as part of a linear process. Second, the old group showed clear segregation into two distinct blocks. Together, these findings exposed critical limitations of the traditional young versus old polarizing analyses, based on a single comparison of extreme phenotypic aging conditions. The next step was identifying DEGs in each decade of life by comparing each age group with the immediately preceding younger one. Following this rational, six lists of DEGs were generated to represent each decade of life between 20 and 80 years of age (Table S10). Though specific gene expression profiles are associated with each decade, one of the most interesting findings related to such an overall analysis is evidence of a dynamic and pattern of epidermal transcription that oscillates with age (Figure 4b).

Continuous gene expression analysis throughout aging

To better understand the continuous gene regulation in sun-exposed epidermal aging, each group was compared to the youngest group (~20 years old). Significant DEGs should present a minimal FC of 1.5 in at least four of the six total comparisons and a minimal FC of 3.0 between the 20- and 80-year-old groups. The p-value cut-off considered was 0.01. Genes complying with those criteria were

subjected to K-means clustering analysis. Several clusters were found, and the most representative clusters were selected for further evaluation, considering a continuous tendency toward an increase or decrease gene expression with age (Figure 5). One cluster evinced the isolated gene SPRR2G as an example of increased expression throughout life (Table S11). Regarding the continuous tendency to reduce gene expression with age, the selected cluster demonstrated 20 modulated probe sets (11 HGNC identified genes), including the keratinization marker LCE1A and the transcription factor CEBPA (also identified in our young versus old analysis and confirmed by qPCR) (Table S11).

Figure 4. Overall analysis of gene expression during sun-exposed epidermal aging using a segmented panel of different decades of life. (A) Hierarchical clustering analysis showing different age groups organized according to similarities in gene expression profile (branches at top). The colored boxes indicate a distribution of decades in preliminary young (blue) versus old (rose) classification. (B) Oscillating transcriptional profile along a lifetime, as indicated by a dashed line

(tendency in the difference between the numbers of up- and down-regulated genes). Each age group was compared to its preceding younger group.

Figure 5. Clustering analysis of genes with similar expression profiles throughout life. (A) Genes with a tendency toward a continuous increase in sun-exposed epidermal aging. (B) Genes with tendency toward continuous decrease in sun-exposed epidermal aging. Each age group was compared with the youngest age group (~20 years old). A complete list of genes can be found in Table S11.

Discussion

In accordance with Rinnerthaler *et al.* (2013) and based on the adoption of different strategies for analysis, this study contributes to the understanding of the dramatic changes that occur in the epidermis during aging. As expected, the main findings were related to modifications in epidermal differentiation and keratinocyte activity/structure. Processes such as cell proliferation were not enriched in our data, possibly because cells from the basal epidermal layer were not likely to be sampled by tape stripping. Considering the fact that samples were collected from the back of hands, this report represents the first study focused on the transcriptome of sun-exposed human epidermal aging.

A comparison of our data with skin-based transcriptome studies (Glass *et al.*, 2013; Yan *et al.*, 2013) indicated the regulation of tissue-specific biological processes, such as epidermis and ectoderm development. However, a comparison

with HAGR data predominantly demonstrated changes in broader biological processes, such as the regulation of cell death and response to chemical stimulus. The high level of interaction between the biomarkers of HAGR cross-analysis – 44 in total – indicates the coordinated regulation of key genes that may simultaneously impact several processes (Figure 3b). Therefore, the epidermis appears to be affected by aging at different levels of molecular regulation, involving impaired broad and tissue-specific biological processes. Mitogen-activated protein kinase 8 (MAPK8) represents a gene that affects the expression of other genes in a cascade effect. This gene responds to activation by environmental stress and proinflammatory cytokines by phosphorylating a number of transcription factors. In addition to the MAPK8 gene, the MAPK signaling pathway was enriched in our analyses, suggesting an epidermal response to constant sun exposition. Akasaka et al. (2010) showed that MAPK8 protein accumulates in sunlight-exposed human epidermises, thereby promoting oxidative stress. Moreover, the MAPK signaling pathway has an indirect link with the Wnt signaling pathway, which was also enriched in our data. Aberrant Wnt signaling contributes to cancerous growth (Castilho et al., 2009), and our findings suggest that it could be related to increase predisposition to cancer development in photoaged skin (Mouret et al., 2011).

It is important to note that several studies have evaluated the effects of aging on the entire skin, but most of these studies have proven to be difficult due to the heterogeneous nature of specimens (Gromov *et al.*, 2003). The extensive list of DEGs presented here reflects our experimental composition (i.e., isolation of the epidermis plus a representative sample size) in association with the simultaneous effects of the intrinsic and extrinsic aging factors on the skin. Interestingly, despite the predominance of up-regulated genes in our data, down-regulated genes had the highest FC values and resulted in a higher number of significantly enriched biological processes (Table 1). Regarding the biological meaning of modulated processes in the comparison between young and old epidermises, seven of the top 10 up-regulated GO terms were related to the deleterious effects on epidermal functions, such as the negative regulation of cellular protein metabolic process, negative regulation of response to stimulus and positive regulation of cell death

(including programmed cell death and apoptosis). The top 10 down-regulated GO terms included processes related to cell differentiation, keratinization and negative regulation of cell death. Some of these results complement or help elucidate the molecular mechanisms behind clinical or morphological epidermal changes. Moreover, establishing comprehensive parallels to other analyses adds significant insight to our data. Apoptosis induction in the photoaged epidermis was previously described as being marked by the presence of sunburn cells or apoptotic keratinocytes (Leyden, 2001; Van Laethem *et al.*, 2005). Such an observation could be supported by our findings of either the induced positive regulation of cell death or the reduced negative regulation of cell death.

According to López-Otín *et al.* (2013), the rate of aging is controlled, at least to some extent, by genetic pathways and biochemical processes that have been conserved throughout evolution, such as the nine emphasized mammalian hallmarks of aging: genomic instability, telomere attrition, epigenetic alterations, loss of proteostasis, deregulated nutrient sensing, mitochondrial dysfunction, cellular senescence, stem cell exhaustion, and altered intercellular communication. A study by Raddatz et al. (2013) highlighted the destabilization of the epigenome as a significant component of epidermal aging, but in contrast with our study, they found that young and old epidermis transcriptomes were similar overall. Because the results of this group were characterized by high expression levels of epidermisspecific genes, we assumed that technical and/or biological limitations did not allow the authors to draw conclusions about broad and conserved regulatory processes. Our identification of DEGs shared with HAGR and the definitions López-Otín et al. (2013) suggest that the age-related modulation of epidermis-specific genes might be accompanied by overall impaired pathways that represent general hallmarks of aging in the entire organism.

A recent study evaluated age-related changes in the composition of the cornified envelope (CE) in human skin (Rinnerthaler *et al.*, 2013). Despite not applying an "omics"-related technique, the expression of 46 genes related to CE formation was evaluated in photo-protected epidermises that were isolated from nine individuals from each of the following age groups: 1-10, 17-44 and 59-74

years. Consistent with our findings, the authors observed no significant changes in the expression of the genes involved in the initial steps of CE assembly, including envoplakin, periplakin and involucrin. Of the five types of transglutaminases (TGMs), the authors identified only a slight increase in TGM1 expression, while we detected a similar result for TGM3. In both studies, the DEGs were mainly related to the processes occurring after scaffold formation, predominantly affecting loricrin (LOR) and the small proline-rich proteins (SPRRs), which correspond to 80% of the CE constitution (Kalinin et al., 2001). Rinnerthaler's group verified the downregulation of LOR and the up-regulation of SPRRs, with the exception of SPRR2G. Increased SPPRs, which function as small bridges between LOR and themselves, were suggested to function in a compensatory mechanism for decreased LOR. In contrast, our data showed increased expression for LOR and some SPPRs, mainly SPPR2G, suggesting that LOR/SPRR expression has distinct patterns of regulation in photo-protected and photo-exposed skin. Nevertheless, inverse LOR regulation could be related to the presence of a thicker epidermis in photoaged skin (Leyden, 2001; El-Domyati et al., 2002), contrary to epidermal thinning in photo-protected areas (Lock-Andersen et al., 1997; Makrantonaki and Zouboulis, 2007). The opposite regulation of LOR expression in photo-protected and photoexposed epidermises resembles elastin regulation in the dermis, whose production is reduced by aging in photo-protected skin, while it is over-expressed in photoaging conditions in the same tissue and leads to elastosis (Uitto, 2008). To date, there is no evidence for SPRR2G regulation with epidermal aging, but several studies have suggested that SPRRs are related to increased epithelial proliferation and the development of malignant processes (Carregaro et al., 2013). Our findings suggest a specific mechanism for epidermal photoaging related to impaired CE formation, which has not been previously described and has potential for further studies in the future.

Because the ionic distribution of calcium drives keratinocytes into differentiation and is inevitable for CE synthesis, Rinnerthaler *et al.* (2013) also evaluated the influence of aging on this biological process and showed that the calcium distribution is different in aged skin, confirming a previous study performed

with facial sun-exposed epidermis (Denda *et al.*, 2003). Our results showed a significant modulation of the calcium signaling pathway in aged epidermises, which is represented by 31 DEGs (Figure 2b). These results represent the first evidence of the molecular mechanisms that are involved in the impairment of the calcium gradient upon epidermal aging, which should be better explored in future studies.

The effects of epidermal photoaging also appear to impair some aspects of the cellular structure, as demonstrated by our findings of modulation of the beta actin (ACTB) gene and the actin cytoskeleton pathway (Figure 2a). Interestingly, ACTB, which is widely used as an endogenous control gene, was up-regulated by epidermal aging in our microarray and gPCR analyses (Figure 1). ACTB modulation might be related to morphological changes in aged keratinocytes in photo-exposed skin areas in which the higher incidence of solar keratosis is associated with diffuse epidermal hyperplasia (Koehler et al., 2011). Previous reports have stated that senescent keratinocytes are irregularly shaped, enlarged and flattened (Soroka et al., 2008), strongly suggesting the impaired regulation of key cytoskeleton components, such as ACTB. Furthermore, actin microfilaments from keratinocytes were shown to be depolymerized by UV radiation (Provost et al., 2003); thus, increased ACTB gene expression could be interpreted as a compensatory mechanism or chronic attempt at damage repair. From a morphological perspective, the regulation of the actin cytoskeletal pathway could be related to the thicker epidermis observed in association with photoaging (Leyden, 2001; El-Domyati et al., 2002).

The young versus old approach used in our study was important for obtaining interesting results and permitting comparisons with relevant previous findings in the literature. However, based on the proposition that aging is a continuous and cumulative process throughout life, we also performed analyses using a segmented panel of volunteers grouped according to different decades of life to understand the real dynamics of sun-exposed epidermal aging. Hierarchical clustering showed that epidermal aging does not appear to represent a linear biological process because different decades of life were not organized in a sequence of crescent age (Figure 4a). The group of 50-year-olds was allocated

closer to the 80-year-old group; however, menopause could help explain this phenomenon because it has already been noted as causing accelerated skin aging (Thornton, 2013). Moreover, the impaired gene expression at 50 years of age appears to be slightly recovered by 60 and 70 years of age, which likely occurs because these groups are clustered closer to the younger group, but they become impaired again at 80 years. Unfortunately, we could not identify clear reasons for this phenomenon, but it suggested an oscillatory pattern of gene expression in the epidermis throughout aging, which has likely been widely neglected because of the number of polarized young versus old analyses. By calculating the difference between the up-regulated and down-regulated genes in each decade, an intriguing profile was revealed, with alternate fluctuations throughout life (Figure 4b). In addition to being a barrier for mechanical protection, the epidermis has been described to be a metabolically active tissue in constant dynamic balance that periodically undergoes complete renewal cycles (Fuchs and Raghavan, 2002). The idea of a constant epidermal dynamic balance suggests the concept of a homeostasis that is characterized by fluctuations requiring readjustment (O'Neill, 2004). López-Otín et al. (2013) stated that several critical questions have arisen in the field of aging regarding, among other factors, the compensatory responses that attempt to reestablish homeostasis. Thus, we have interpreted the molecular behavior of the epidermis throughout aging as a continuous attempt at homeostatic regulation based on successive rounds of feedback response. The highest oscillation in terms of gene expression occurs at approximately 30 years of age, which is in accordance with the publication of Kuwazuru et al. (2012), who stated that skin wrinkling morphology suddenly changes in the early 30s based on the evaluation of facial skin from 102 women aged 25-56 years. However, the amplitude of the fluctuation appears to decrease over a lifetime (which means a lower number of regulated genes), possibly suggesting that homeostatic mechanisms deteriorate with epidermal aging (O'Neill, 2004). According to Kirkwood (2005), aging involves cumulative changes that affect the ability to adaptively respond to stress. Notably, a ten-year interval between two sequential groups may be too large to infer causal relationships, which was not our intention.

Nevertheless, the use of segmented intervals appears to represent an advantage for the continuous evaluation of aging, thereby enriching data interpretation.

An additional analysis, which used the panel of volunteers segregated by decades of age, was conducted to identify genes that tend to change continuously throughout life. SPPR2G represented the most significant up-regulated gene (Figure 5a). Because SPPR2G was not modulated in the study of Rinnerthaler et al. (2013), we believe that it represents a strong candidate for epidermal aging specifically associated with photoaged conditions. Additionally, the homologous family of SPRRs appears to have the greatest age-related changes in the CE occurring as a life-long process (Rinnerthaler et al., 2013). In the continuously down-regulated genes (Figure 5b), we identified the keratinization marker LCE1A. This gene represents a protein that is involved in the last step of CE assembly and was found to be down-regulated during epidermal aging in the study by Rinnerthaler et al. (2013). In this case, in addition to differences related to photoexposed or photo-protected areas, decreased levels of LCE1 members can be expected to be a result of reduced calcium levels in the aged epidermis. Another continuously down-regulated gene was the transcription factor CEBPA, which was also identified in the young versus old analysis and confirmed by qPCR. CEBPA is a basic leucine zipper transcription factor that is abundantly expressed in keratinocytes and whose function in skin is poorly characterized. Under UVB radiation, CEBPA is induced in keratinocytes, participates in cell cycle checkpoints that arrest cell cycle progression and prevents the replication of damaged DNA (Yoon K and Smart, 2004). Our evidences of gene expression reduction in the epidermis upon aging, using different analysis and techniques, suggests that CEBPA is an important element that is associated with an increased predisposition to cancer development in photoaged skin (Mouret et al., 2011).

Given the functional importance of the epidermis to the homeostasis of an organism and the necessity of better understanding of the molecular mechanisms underlying epidermal aging, this study critically evaluated the changes affecting the epidermis throughout life, including intrinsic and extrinsic factors. With the main objective of this study being to open new perspectives for skin aging evaluation, we

presented alternative analyses that consider aging to be a continuous process. Future perspectives could include elucidating the specific mechanisms associated with epidermal aging to allow for the development of potential therapeutic approaches.

Conflict of Interests

LINC00334	long intergenic non-protein coding RNA 334	1,84	Up
GUCD1	quanylyl cyclase domain containing 1	1.53	Un
C22orf20	chromosome 22 open reading frame 20	156	Down
02201123	single pass membrane protein with an enterty 1	1,00	DO MII
SM DT1	single-pass memorane protein with aspartate-rich	1.97	Up
	tail 1		- ٣
TM EM 184B	transmembrane protein 184B	1,76	Up
KIAA0930	KIAA0930	2 81	Un
		2,01	ЧU
CNPPD1	cyclin Pas1/PHO80 domain containing 1	1,91	Up
	-		

MMADHC	methylmalonic aciduria (cobalamin deficiency) cbID type, with homocystinuria	1,71	Up
DRC1	dynein regulatory complex subunit 1 homolog	1,64	Down
MAATS1	(Chiamydomonas) MYCBP-associated, testis expressed 1	1,80	Up
C3orf27	chromosome 3 open reading frame 27	1,74	Up
SSUH2	ssu-2 homolog (C. elegans)	1.78	Un
HMCES	5-hydroxymethylcytosine (hmC) binding, ES cell-	165	Up
Fill CE3	specific	1,00	Up
530138	family with appunded similarity 10.4 member A	1,70	Up
FAM 194A	Taniny with sequence similarity 194, member A	1,90	Up
C3orf58	chromosome 3 open reading frame 58	1,59 2,19	Up Down
M B21D2	M ab-21 domain containing 2	1,62	Up
NDUFAF3	NADH dehydrogenase (ubiquinone) complex I, assembly factor 3	1,55	Up
C3orf62	chromosome 3 open reading frame 62	1,57	Up
WDFY3-AS2	WDFY3 antisense RNA 2	1,59	Up
NOA 1 C4 orf 17	nitric oxide associated 1 chromosome 4 open reading frame 17	1,66 1,77	Up Up
TRM T44	tRNA methyltransferase 44 homolog (S. cerevisiae)	1,50	Up
PACRGL	PARK2 co-regulated-like	1.51	Down
C5AR1	complement component 5a receptor 1	1,61	Up
C5orf20	chromosome 5 open reading frame 20	3,28	Down
FAM1/2A GAPT	family with sequence similarity 1/2, member A GBB2-binding adaptor protein transmembrane	1,52 1,51	Down
SETD9	SET domain containing 9	1,50	Up
FAM 13B	family with sequence similarity 13, member B	1,75	Up
C6orf 106	chromosome 6 open reading frame 106	1,64	Up
CCDC167	Colled-coll domain containing 167	1,89	Up
OARD1	O-acyl-ADP-ribose deacylase 1	1,67	Up
ATAT1	alpha tubulin acetyltransferase 1	1,62	Up
AKIRIN2	akirin 2 failed even connections homelog (Droconhile)	1,83	Up
SLC18B1	solute carrier family 18, subfamily B, member 1	1,57	Up
C6orf203	chromosome 6 open reading frame 203	1,52	Up
RSPH9	radial spoke head 9 homolog (Chlamydomonas)	1,61	Up
VWA7	von Willebrand factor A domain containing 7	1,98	Down
C6orf62	chromosome 6 open reading frame 62	1.87	Up
BEND6	BEN domain containing 6	1,60	Up
GINM 1	glycoprotein integral membrane 1	1,82	Up
BRAT1	BRCA1-associated ATM activator 1	1,51	Up
C7orf34	chromosome 7 open reading frame 34	1,66	Up
COA1	cytochrome c oxidase assembly factor 1 homolog (S.	1,56	Up
FAM 167A	family with sequence similarity 167, member A	1.75	Down
C8orf15~withdr awn	entry withdrawn	1,64	Up
C8orf31	chromosome 8 open reading frame 31	1,82	Up
C8orf34	chromosome 8 open reading frame 34	1,63	Up
UTP23	component, homolog (yeast)	1,65	Up
UTP23	UTP23, small subunit (SSU) processome component, homolog (veast)	1,54	Down
FER1L6-AS1	FER1L6 antisense RNA 1	1,77	Up
C8orf60	chromosome 8 open reading frame 60	1,79	Up
ARIGEF39	excision repair cross-complementing rodent repair	1,07	Up
ERCC6L2	deficiency, complementation group 6-like 2	1,89	Up
EQTN	equatorin, sperm acrosome associated	1,51	Up
LINC00476	long intergenic non-protein coding RNA 476	י∠ס,ו 1,70	ορ Ορ
C9orf 135	chromosome 9 open reading frame 135	1,88	Up
C9orf 139	chromosome 9 open reading frame 139	1,63	Down
M ORN5	MORN repeat containing 5	1,73	Up
LINC00474 GSN-AS1	iong intergenic non-protein coding RNA 474 GSN antisense RNA 1	1,54 1,55	Up Un
C9orf37	chromosome 9 open reading frame 37	1,60	Up
C9orf37	chromosome 9 open reading frame 37	1,84	Up

OR8H1	pseudogene olfactory receptor, family 8, subfamily H, member 1	1,84	Up
OR8U1	olfactory receptor, family 8, subfamily U, member 1	1,71	Up
ORC2	origin recognition complex subunit 2	1.63	Up
ORM DL3	ORM 1-like 3 (S. cerevisiae)	2,21	Up
OSBP OSBP 40	oxysterol binding protein	1,73	Down
OSB PL 10	oxysterol binding protein like 10	1,09	Up
OCD DI 14		1.55	<u>ор</u>
OSBPLIA OSBPL8	oxysterol binding protein-like IA	1,55 1,75	Up
OSBPL9	oxysterol binding protein-like 9	1,52	Up
OSM R OSB2	oncostatin M receptor odd-skipped related transciption factor 2	1,68 166	Up
OSTF1	osteoclast stimulating factor 1	1,99	Up

OSTM 1	osteopetrosis associated transmembrane protein 1	1.53	Un
OTOF	otoferlin	1,95	Down
OTOP2	otopetrin 2	1,62	Up
OTUDI	OTU de mais se staising 1	100	11-
OTUDT		1,69	Op
OXGR1	oxoglutarate (alpha-ketoglutarate) receptor 1	1,56	Up
OXR1	oxidation resistance 1	2,19	Up
OXSM	3-oxoacyl-ACP synthase, mitochondrial	1,51	Up
RPRD1A	regulation of nuclear pre-mRNA domain containing 1A	1,91	Up
P2RX3	purinergic receptor P2X, ligand-gated ion channel, 3	1,69	Up
P2RX6	purinergic receptor P2X, ligand-gated ion channel, 6	1,94	Down
P4HB	prolyl 4-hydroxylase, beta polypeptide	1,70	Up
TP53AIP1	protein 1	1,79	Up
PABPC1	poly(A) binding protein, cytoplasmic 1	1,59	Up
PACRG	PARK2 co-regulated protein kinase C and casein kinase substrate in	1,81	Up
PACSIN3	neurons 3	1,50	Up
PADI4	peptidyl arginine deiminase, type IV	1,90	Up
PAG1	microdomains 1	1,61	Up
PAIP1	poly(A) binding protein interacting protein 1	1,79	Up
PAIP2B	poly(A) binding protein interacting protein 2B	1,79	Up
PANX3	pannexin 3	1,59	Up
PAPLN	papilin, proteoglycan-like sulfated glycoprotein	1,66	Up
PAPSS2	3'-phosphoadenosine 5'-phosphosulfate synthase 2	1,76	Up
DAODR		1 57	- 1-
	progestin and adipoQreceptor family member VIII	1,57	Up
PARD3B	par-3 family cell polarity regulator beta	1,89	Up
PARG	poly (ADP-ribose) glycohydrolase	1,84	Up
PARP1	poly (ADP-ribose) polymerase 1	1,81	Up
PARP10 PARP2	poly (ADP-ribose) polymerase family, member 10 poly (ADP-ribose) polymerase 2	1,55 1.52	Uown Up
PATE1	prostate and testis expressed 1	1,66	Up
PAX1	paired box 1	1,65	Up
PAX3	paired box 3	1,80	Up
PAX5	paired box 5	1,77	Up
PAX6 PAX7	paired box 6 paired box 7	1,55	Up Up
PBLD	phenazine biosynthesis-like protein domain	1,53	Up
PBX2	containing pre-B-cell leukemia homeobox 2	1,72	Up
PC	, pyruvatecarboxylase	2,11	Down
PCBP4	poly(rC) birding protein 4	152	Un
PCDH10	protocadherin 10	1.81	Un
PCDHI	protocadherin 7	1,01	Up
		1,75	Dawa
PCDHR12	protocadherin heta 12	1,51	Up
PCDHB9	protocadherin beta 9	1,77	Un
PCDHGA7	protocadherin gamma subfamily A. 7	2.14	Down
PCDHGA8	protocadherin gamma subfamily A 8	2.50	Un
PCDHGA9	protocadherin gamma subfamily A, 9	1,57	Up
PCDHGB1	protocadherin gamma subfamily B, 1	2,12	Up
PCDHGC4	protocadherin gamma subfamily C, 4	1,56	Up
PCGF1	polycomb group ring finger 1	2,26	Up
PCGF5	polycomb group ring finger 5	1,96	Up
PCK2	phosphoenolpyruvate carboxykinase 2	1,63	Up
PCLO	piccolo presynaptic cytomatrix protein	1,55	Up
PCM T1	protein-L-isoaspartate (D-aspartate) O-	2,54	Up
PCNXL3	pecanex-like 3 (Drosophila)	2,18	Up
PCNXL3	pecanex-like 3 (Drosophila)	2,48	Down
PCOLCE	procollagen C-endopeptidase enhancer	1,61	Up
PCSK1N	proprotein convertase subtilisin/kexin type 1	1,62	Down
PCSK1N	proprotein convertase subtilisin/kexin type 1	2,34	Down
PCSK6	וחום ונסר proprotein convertase subtilisin/kexin tvpe 6	1,60	Up
CDK16	cyclin-dependent kinase 16	1,53	Up
PDCD1	programmed cell death 1	1,96 1 71	Up
PDCD4	programmed cell death 4 (neoplastic transformation	108	Un
PDCIA	inhibitor) phoseducio-like 3	1 75	115
PDE1B	phosphodiesterase 1B, calmodulin-dependent	1,75	Up
PDE1C	phosphodiesterase 1C, calmodulin-dependent 70kDa	1,61	Up
PDE4C	phosphodiesterase 4C, cAM P-specific	2,08	Up
PDE4D	phosphodiesterase 4D, cAMP-specific	1,62	Up
PDE6B	pnospnodiesterase 6B, cGM P-specific, rod, beta	1,79	Up

PDIA3	protein disulfide isomerase family A, member 3	1,63	Up
PDIA3	protein disulfide isomerase family A, member 3	1,51	Up
PDIA6	protein disulfide isomerase family A, member 6	1,56	Up
PDPK1	3-phosphoinositide dependent protein kinase-1	1,53	Up
PDRG1	p53 and DNA-damage regulated 1	1,63	Up
PDXDC2P	pyridoxal-dependent decarboxylase domain	1,50	Up
DDVK	containing 2, pseudogene	100	Lin
PUXK	pyridoxai (pyridoxinė, vitamin B6) kinase	1,89	Up
PDZD11	PDZ domain containing 11 PDZ domain containing ring finger 4	1,53	Up
ECI2	enoyl-CoA delta isomerase 2	1,87	Up
PELI2	pellino E3 ubiquitin protein ligase family member 2	1,95	Up
PENK	proenkephalin	1,56	Down
PER2	period circadian clock 2	1,72	Up
PES1	pescadillo ribosomal biogenesis factor 1	1,63	Up
PEX 10	peroxisomal biogenesis factor 10	1,68	Up
PF4	platelet factor 4	1,76	Up
PFKFB1	biphosphatase 1	1,57	Down
PFKFB2	biphosphatase 2	2,00	Up
PFKL	phosphofructokinase, liver	1,52	Down
PFKL	phosphofructokinase, liver	3,04	Down
PEN1	profilin 1	1,51	Down
PFN3	profilin 3	1,58	Down
PGAM 5	phosphoglycerate mutase family member 5	1,72	Up
PGAP1	post-GPI attachment to proteins 1	1,50	Up
PGK1	phosphoglycerate kinase 1	1,59	Up
PGLY RP1	peptidoglycan recognition protein 1	1,59	Up
PGLY RP3	peptidoglycan recognition protein 3	1,54	Up
PGRM C2	progesterone receptor membrane component 2	1,84	Up
PGRIVIC2 PHACTR4	phosphatase and actin regulator 4	2.01	Up Up
PHF12	PHD finger protein 12	1,78	Up
JADE1	iade family PHD finger 1	1.53	Up
PHF20L1	PHD finger protein 20-like 1	1,65	Up
PHF23	PHD finger protein 23	1,53	Up
PHF7	PHD finger protein 7	2,60	Down
PHKG2	phosphorylase kinase, gamma 2 (testis)	1,74	Up
PHLDB2	pleckstrin homology-like domain, family B, member 2	2,12	Up
PHLPP2	PH domain and leucine rich repeat protein	2,01	Up
PHOY24	phosphatase 2	155	Down
PHYHD1	phytanoyl-CoA dioxygenase domain containing 1	1,58	Up
PIAS4	protein inhibitor of activated STAT, 4	1,67	Down
INPP5J	inositol polyphosphate-5-phosphatase J	1,62	Up
PID1	phosphotyrosine interaction domain containing 1	1,69	Up
PIGG	phosphatidylinositol glycan anchor biosynthesis, class G	1,96	Up
PIGN	phosphatidylinositol glycan anchor biosynthesis, class N	1,92	Up
PIGR	polymeric immunoglobulin receptor	1,97	Up
PIGT	phosphatidylinositol glycan anchor biosynthesis, class T	1,60	Up
PIGU	phosphatidylinositol glycan anchor biosynthesis, class U	1,70	Up
PIGX	phosphatidylinositol glycan anchor biosynthesis, class X	1,70	Up
PIGY	phosphatidylinositol glycan anchor biosynthesis, class Y	1,56	Up
PIK3CG	phosphatidylinositol-4,5-bisphosphate 3-kinase,	1,85	Up
PILRA	paired immunoglobin-like type 2 receptor alpha	1,52	Up
PIP5K1C	phosphatidylinositol-4-phosphate 5-kinase, type I,	2.73	Down
DIKEVVE	gamma	155	Un
PIR	pirin (iron-binding nuclear protein)	1,57	Up
PISD	phosphatidylserine decarboxylase	2,19	Up
PITPNM 2	phosphatidylinositol transfer protein, membrane-	1,61	Up
PITPNM3	associated 2 PITPNM family member 3	189	Un
PKD1L3	polycystic kidney disease 1-like 3	1,65	Up
PKD2L2	polycystic kidney disease 2-like 2	1,58	Up
PKIA	protein kinase (cAM P-dependent, catalytic) inhibitor	1,53	Up
PKN2	aipna protein kinase N2	1,56	Up
PKN2	protein kinase N2	1,87	Up
PKN2	protein kinase N2	1,62	Down
PKNOX1	PBX/knotted 1 homeobox 1	1,58	Up
PKNUX1 PLA2G1B	PBX/KNOTTED 1 NOMEODOX 1	1,67 164	Up

RASGEF1A	RasGEF domain family, member 1A	1,85	Up
RASGRP1	RAS guanyl releasing protein 1 (calcium and DAG-	1,55	Up
RASGRP2	RAS guanyl releasing protein 2 (calcium and DAG-	1.52	Up
DASCODA	regulated)	160	
nA3GhF4	nas guaryi releasing protein 4	1,09	υp
RASL11A	RAS-like, family 11, member A	1,61	Up
RAVER1	ribonucleoprotein, PTB-binding 1	1,93	Up
RB1	retinoblastoma 1	1,57	Up
RBBP9	retinoblastoma binding protein 9	1,67	Up
RBKS	ribokinase	1,65	Up
RBM 15B	HNA binding motif protein 15B	1,92	Up
RBM23	RNA binding motif protein 23	1,51	Up
ESRP2	epithelial splicing regulatory protein 2	2,42	Up
RBM 38	RNA binding motif protein 38	1,55	Up
	RNA binding motif.single stranded interacting	1,06	uр
KRW 23	protein 3	1,73	Up
RBM XL1	RNA binding motif protein, X-linked-like 1	1,63	Up
RBM Y2FP	RNA binding motif protein, Y-linked, family 2, member F pseudogene	1,67	Up
RBPJ	recombination signal binding protein for	1,71	Up
	mmunogiobulin kappa Jiegion		

	regulator of chiomosome condensation 2	1,77	Up	PIBP3
RCL1	RNA terminal phosphate cyclase-like 1	2,50	Down	ROR1
CRCP	CGRP receptor component	1,70	Up	RORB
RDH8	retinol dehydrogenase 8 (all-trans)	1,54	Up	RORC
BEEP3	recentor accessory protein 3	165	Un	BP2
DEEDC	receptor accessory protein 6	1.50	Down	
DECID	receptor accessory protein o	1,00	DOWIN	DDL40A
REGID	regeneraling islet-derived i beta	1,60	Up	RPLIUA
RELA	v-rei avian reticulo end otnellosis viral oncogene	1,58	Up	RPL10L
	homolog A			
REPIN1	replication initiator 1	1,67	Up	RPL13
REPIN1	replication initiator 1	1,76	Up	RPL13A
RETNLB	resistin like beta	1,52	Up	RPL14
BEXO1	BEX1 BNA exonuclease 1 homolog (S. cerevisiae)	180	Un	BPI 22
REX 02	RNA exemuclease 2	2 20	Un	PPI 22
DECO	replication forter C (activator 1) 2, 281/De	1.00	Up Up	DDI 001 1
RFG3	replication factor G (activator i) 3, 36kDa	1,69	Up	RPLZZLI
RFK	riboflavin kinase	1,91	Up	RPL23
BEX2	regulatory factor X, 2 (influences HLA class II	172	Un	BPI 23A
111712	expression)	.,	οp	111 22 07 1
ARHGEF28	Rho guanine nucleotide exchange factor (GEF) 28	1,80	Up	RPL26L1
RGPD1	BANBP2-like and GBIP domain containing 1	1.60	Un	BPL28
RGS11	regulator of G-protein signaling 11	2.08	Un	BPI 29
RCS2	regulator of G protein signaling 2, 24kDa	150	Up	PRI 20 P2
RG32	regulator of G-protein signaling 2, 24KDa	1,50	Up Up	RFL29F2
RGS20	regulator of G-protein signaling 20	1,51	Up	RPL36A
RGS4	regulator of G-protein signaling 4	1,64	Up	RPL7A
RGSL1	regulator of G-protein signaling like 1	1,81	Up	RPLP2
RHBDD1	rhomboid domain containing 1	1,66	Up	RPP21
RHBDD3	rhomboid domain containing 3	1.58	Down	RPP25
BHBDI 1	rhomboid veinlet-like 1 (Drosophila)	2 53	Down	BPS13
	rhombold, veiniet like 2 (Dresenbile)	1 5 4	LI-	DDC14
RHBULS	rhombold, veiniet-like 3 (Drosophila)	1,54	Up	RF514
RHCG	Rh family, C glycoprotein	1,77	Up	RPS15A
RHEBL1	Ras homolog enriched in brain like 1	1,94	Up	RPS19
RHO	rhodopsin	1,80	Up	RPS19
RHOA	ras homolog family member A	1.67	Un	BPS26
BHOA	ras homolog family member A	154	Un	BPS27
RUOC		1.04	Up Up	DDC00
RHOC	ras homolog ramity member C	1,94	Up	RP526
RHOG	ras homolog family member G	2,35	Up	RPS28
RHOT1	ras homolog family member T1	1,55	Up	RPS29
RHPN1	rhophilin, Rho GTPase binding protein 1	2,77	Down	RPS3A
RHPN2	rhophilin, Rho GTPase binding protein 2	1,53	Up	RPS4X
BIE1	BAP1interacting factor homolog (yeast)	156	Un	BPS6
DIM B D2	RIMS binding protein?	102	Un	BBS6KA1

	receptor 3		
KIAA0513	KIAA0513	VIMP	VCP-interacting membrane protein
			sema domain, seven thrombospondin repeats (type 1 and type 1-like)
KIAA0586	KIAA0586	SEM A5B	transmissing densities (TM) and shart a start leaving densities (spectrum),
			transmenorane domain (TW) and short cytophasmic domain, (semaphorn) 55
KIAA0753	KIAA0753	M SRB1	methionine sulfoxide reductase B1
144110	MALIO states show with a shortes (sates	OFRIDINUM	serpin peptidase inhibitor, clade H (heat shock protein 47), member 1, (collagen
MAUZ	MAU2 sister chromatid conesion factor	SERPINHI	binding protein 1)
KIA A 0007	KIA A 0007	CEODE	enlines fotor 1/
KIAAU907	KIAA0907	3F3B5	splicing factor 30, subulit 5, lokDa
ZSWIM 8	zinc finger, SWIM -type containing 8	SGPP2	sphingosine-1-phosphate phosphatase 2
KLHDC3	kelch domain containing 3	SHB	Src homology 2 domain containing adaptor protein B
KBT27	keratin 27	SHE	Src homology 2 domain containing E
KDT20	keretin 20	CIDTO	CID 1 transmith range family, member 0
KH132	Keralii 32	3012	SiD i transhembrane ranniy, member 2
KRT34	keratin 34	SLC10A3	solute carrier family 10, member 3
1/270.0	1		
KH138	keratin 38	SLC11A2	solute carrier family 11 (proton-coupled divalent metal ion transporter), member 2
KDTC	Location E	01.040.4.5	
KH I 5	Keratin 5	SLC IDA5	solute carrier family is (monocarboxylate transporter), member 5
KRT85	keratin 85	SLC25A1	solute carrier family 25 (mitochondrial carrier; citrate transporter), member 1
KRT86	keratin 86	SLC25A42	solute carrier family 25, member 42
KRTAP10.1	keratin associated protein 19-1	SI C 2 4 5	solute carrier family 2 (facilitated glucose/fructose transporter) member 5
KDTADAO	keratin associated protein is-1	OLOZAJ	solute carrier family 2 (racinated globolar naciose nacional nacional di solute carrier family 2 (racinated globolar nacional di solute
KRIAP4-2	keratin associated protein 4-2	SLC35B1	Solute carrier family 35, member B I
KRTAP4-5	keratin associated protein 4-5	SLC35F1	solute carrier family 35, member F1
KRTAP9-3	keratin associated protein 9-3	SLC37A4	solute carrier family 37 (glucose-6-phosphate transporter), member 4
KRTAP9-4	keratin associated protein 9-4	SI CA 1A 1	solute carrier family 41 (magnesium transporter) member 1
DOOLUTA	Relatinassociated proteins -+		solute carries family 4 (magnesian ransporter), neutron
POGLUTT	protein O-glucosyltransferase I	SLC45A2	solute carrier family 45, member 2
LENG	LENG O-fucesylpentide 3-beta-N-acetylalucesaminyltransferase	SI C47A 1	solute carrier family 47 (multidrug and to vin extrusion) member 1
LING	Er Ner O-Tacosylpeptide 5-beta N-acetylgiacosaninytransierase	GEOTIAT	solute carrier raminy 47 (marticiting and toxinextrusion), member r
LGALS1	lectin galactoside-binding soluble 1	SLC7A1	solute carrier family 7 (cationic amino acid transporter y+ system) member 1
LOALOO	lastia adastasida biadias askibla 0	01.01	Old Od have better by Control of the control and the temporter, yit by other, the board
LGALS8	lectin, galactoside-binding, soluble, 8	SM G1	SM G1 phosphatidylinositol 3-kinase-related kinase
LRP3	low density lipoprotein receptor-related protein 3	SND1	staphylococcal nuclease and tudor domain containing 1
LBBC18	leucine rich repeat containing 18	ABHGAP33	Bho GTPase activating protein 33
NPPOS	possible regulator of reactive exugen encoire	SDEN	an an family transprintional concerns
NHHU3	negative regulator of reactive oxygen species	SPEN	spentanily transcriptional repressor
LSS	lanosterol synthase (2,3-oxidosqualene-lanosterol cyclase)	SPG11	spastic paraplegia 11 (autosomal recessive)
LYG2	lysozyme G-like 2	SPRR 1A	small proline-rich protein 1A
MAPIA	microtubule-sesociated protein 14	SPTI C3	sarina nalmitoultransfarasa long chain basa subunit 3
		00 1200	serie painto yrraisie ase, forg chan base subunit o
MAPKBPI	mitogen-activated protein kinase binding protein i	SREBFI	sterol regulatory element binding transcription factor i
MC5R	melanocortin 5 receptor	SSH3	slingshot protein phosphatase 3
ME1	malic enzyme 1, NADP(+)-dependent, cytosolic	STK31	serine/threonine kinase 31
MEA 1	male-enhanced antigen 1	SULT/ A1	sulfatransferaça family 4.4. member 1
MEODE		0021441	survey a second se
MFSD5	major facilitator superfamily domain containing 5	SYNGRI	synaptogyrin i
MIDEODUC	MIDE02 heat game (non-protein as ding)	TA C 10	TAF10 RNA polymerase II, TATA box binding protein (TBP)-associated factor,
MINJUJINA	windud lost gene (non-protein county)	TALIO	30kDa
ΜΙΔΝΔ	malan-A	TAP1	transporter 1 ATP-binding cassette sub-family B (MDB/TAP)
	molar-A	TADDDD	TAB DONIE , ATT-binding cassette, sub-tanny b (wibiti TAT)
MMRN1	multimerin 1	TARDBP	TAR DNA binding protein
MOCS1	molybdenum cofactor synthesis 1	TBC1D2	TBC1 domain family, member 2
MOGAT1	monoacvlolvcerol O-acvltransferase 1	TCN2	transcobalamin II
M BPS12	mitochondrial ribosomal protein S12	TEX 264	testis expressed 264
MITTOR	mitochondrial ribosonial protein 012	TEREO	
MRP524	mitochonorial ribosomal protein 524	IFF3	treroli factor 3 (Intestinai)
MRPS25	mitochondrial ribosomal protein S25	THOC1	THO complex 1
MSRA	methionine sulfoxide reductase A	THY 1	Thy-1 cell surface antigen
MSY1	meh homeo hov 1	TIAP1	tight junction associated protein 1 (peripheral)
NADOD	and a Descention of the second second	THENAL	
NAPSB	napsin B aspartic peptidase, pseudogene	I M EM 14 1	transmembrane protein 141
NDUEAR	NADH debydrog oppose (ubiguine po) 1 ale be subcorregiov, 9, 10kDa	TM EM 179 A	transmombrana protain 179 A
NDOFAG	INADITUEllyutogeliase (ubiquitorie) Taipita subcomplex, 6, 15KDa	TIVI LIVI 1/6A	transmenurane protein non
NDUFB2	NADH dehydrogenase (ubiquinone) 1 beta subcomplex, 2, 8 kDa	TM EM 31	transmembrane protein 31
NKD2	naked cuticle homolog 2 (Drosophila)	TM EM 50 B	transmembrane protein 50B
OA71	ornithine decarboxylase antizyme 1	TM FM 71	transmembrane protein 71
OLEWI 2P	olfactomedin-like 2B	TM EM 07	transmembrane protein 97
	evicia recenzibile e complete etheralt O	TNEDOE01	times served feater recenter or starting of At
UHG2	origin recognition complex, subunit 2	INFRSF21	cumor necrosis ractor receptor superramity, member 21
PADI4	peptidyl arginine deiminase, type IV	TNFRSF25	tumor necrosis factor receptor superfamily, member 25
PAPI N	papilin, proteoglycan-like sulfated glycoprotein	TRAK1	trafficking protein, kinesin binding 1
DADDO	poly (ADP ribase) polymerase 2	TDDV4	transient recenter potential ention phoneni subfamily V member 1
FARE2	pory (ADF-TIDOSE) poryfilei ase 2	TERMO	transion, receptor potential cation channels, subtaining V, member 1
PC	pyruvat e carbo xylase	TRPV2	transient receptor potential cation channel, subfamily V, member 2
PCDH7	protocadherin 7	TTYH3	tweety family member 3
PCK2	nhosphoenolovruvate carboxykinase 2 (mitochondrial)	TURGOPS	tubulin, gamma complex associated protein 6
PDEAC	nhoenhodigetarsea (C. cAMP apositio	10211	uridine-outidine kinsee 1-like 1
PDE40	prosphodiesterase 40, CAIVIE-specific	UCKLI	unumercytlume kinase Flike I
PGAM 5	phosphoglycerate mutase family member 5	UCN2	urocortin 2
PHF12	PHD finger protein 12	UQCR10	ubiquinol-cytochrome c reductase, complex III subunit X
PHF7	PHD finger protein 7	I ISDI 1	ubiquitin specific pentidase like 1
DION	n he en het id die eite bei einen en die eine bei einet die bei bei	UAU?	uni a manine minine internet de mentre de traterio
PIGN	prosphaticition grycan anchor biosynthesis, class N	VAV3	vav o guanine nucleotide exchange factor
PISD	phosphatidylserine decarboxylase	YTHDC1	YTH domain containing 1
PLCH2	phospholipase C, eta 2	ZDHHC24	zinc finger, DHHC-type containing 24
	patatin-like phospholingse domain containing 5		zinc finger, DHHC-type containing 8
FINPLAD	paramente prosprioripase d'ornant contraining 5		zine ringer, Driftertype containing o
PON3	paraoxonase 3	ZFYVE20	zinc ringer, FYVE domain containing 20
PPP1R11	protein phosphatase 1, regulatory (inhibitor) subunit 11	ZFYVE26	zinc finger, FYVE domain containing 26
PPP2R1B	protein phosphatase 2, regulatory subunit A, beta	ZNF333	zinc finger protein 333
PRM T2	protein arginine methyltransferase ?	7NE525	zinc finger protein 525
F DDD 1	proton alginine methylitansierase 2	ZINF020	zine ringer protein az a
PKK4	proline rich 4 (lacrimal)	ZINE581	zind ringer protein 58 i

PNM A3	paraneoplastic M a antigen 3	TDRD10	tudor domain containing 10
PNPO	pyridoxamine 5'-phosphate oxidase	TENC1	tensin like C1 domain containing phosphatase (tensin 2)
POL B2I	nolymerase (BNA) II (DNA directed) nolymentide L 76kDa	TEX264	testis expressed 264
PPAPDC1B	nhosnhatidic acid nhosnhatase type 2 domain containing 1B	TGEBB2	transforming growth factor, beta recentor II (70/80kDa)
PPP2B1B	prospharate actor prospharase type 2 domain containing its	THSD7B	thrombospondin type L domain containing 7B
DDD/	protion phosphatase 2, regulatory subunit A, beta	TLES	transducin like ophonor of colit 6 (E(col) homolog. Droconbile)
	promericity (acrimal)	THOOL	transouch-like einancei of spiit 6 (E(spi) homolog, brosophila)
	parathyroto normone-like normone	TMDDCCC	transmembrane protesse, sering 6
	quescin do sullivoryi oxidase 2	TOMALA	transmembrane protease, serine o
RAPGEFI	Rap guanine nucleotide exchange ractor (GEF) 1	TOWILI	target of myb I (chicken)-like I
RBM 53	RIVA binding motil, single stranded interacting protein 3	IPGNI	two pore segment channel 1
RBPJ	recombination signal binding protein for immunoglobulin kappa. J region	TPD52L1	tumor protein D52-like 1
RFC3	replication factor C (activator 1) 3, 38kDa	TPSG1	tryptase gamma 1
RGS4	regulator of G-protein signaling 4	TSPAN18	tetraspanin 18
RHBDL3	rhomboid, veinlet-like 3 (Drosophila)	TWIST2	twist family bHLH transcription factor 2
RHPN2	rhophilin, Rho GTPase binding protein 2	UBE2Q2	ubiquitin-conjugating enzyme E2Q family member 2
RNF175	ring finger protein 175	UBTD2	ubiquitin domain containing 2
RORB	RAR-related orphan receptor B	VANGL1	VANGL planar cell polarity protein 1
RPH3AL	rabphilin 3A-like (without C2 domains)	VEGFA	vascular endothelial growth factor A
RSU1	Ras suppressor protein 1	VIP	vasoactive intestinal peptide
S100A3	S100 calcium binding protein A3	DPH7	diphthamide biosynthesis 7
SAMD10	sterile alpha motif domain containing 10	WFDC5	WAP four-disulfide core domain 5
SCARF2	scavenger receptor class F, member 2	WNK4	WNK lysine deficient protein kinase 4
SCGB 1D2	secretoglobin, family 1D, member 2	WNT5B	wingless-type MMTV integration site family, member 5B
SDSL	serine dehydratase-like	XYLB	xylulokinase homolog (H. influenzae)
SEC23B	Sec23 homolog B (S. cerevisiae)	YBX2	Y box binding protein 2
VIMP	VCP-interacting membrane protein	YTHDC1	YTH domain containing 1
SETBP1	SET binding protein 1	YWHAQ	tyrosine 3-monooxygenase/tryptophan 5-monooxygenase activation protein, theta
SH3BGRL	SH3 domain binding glutamic acid-rich protein like	ZM YND 12	zinc finger, MYND-type containing 12
SH3 GL3	SH3-domain GRB2-like 3	ZNF326	zinc finger protein 326
1. Information from HG	NC (HUGO Gene Nomenclature Committee; www.genenames.org).	1. Information from HGN	IC (HUGO Gene Nomenclature Committee; www.genenames.org).

Table S9. Epidermal age-modulated genes shared with Human Ageing Genomic Resources (HAGR).

HGNC Approved		HGNC Approved	
Symbol ¹	HGNC Approved Name ¹	Symbol ¹	HGNC Approved Name ¹
BAK1	BCL2-antagonist/killer 1	NRG1	neuregulin 1
CDC42	cell division cycle 42	PARP1	poly (ADP-ribose) polymerase 1
CEBPA	CCAAT/enhancer binding protein (C/EBP), alpha	PCMT1	protein-L-isoaspartate (D-aspartate) O-methyltransferase
CETP	cholesteryl ester transfer protein, plasma	PDPK1	3-phosphoinositide dependent protein kinase-1
COQ7	coenzyme Q7 homolog, ubiquinone (yeast)	PLCG2	phospholipase C, gamma 2 (phosphatidylinositol-specific)
DBN1	drebrin 1	PML	promyelocytic leukemia
EIF5A2	eukaryotic translation initiation factor 5A2	PROP1	PROP paired-like homeobox 1
ELN	elastin	PTK2B	protein tyrosine kinase 2 beta
ESR1	estrogen receptor 1	RAD52	RAD52 homolog (S. cerevisiae)
FEN1	flap structure-specific endonuclease 1	RB1	retinoblastoma 1
GHRHR	growth hormone releasing hormone receptor	RELA	v-rel avian reticuloendotheliosis viral oncogene homolog A
GSK3A	glycogen synthase kinase 3 alpha	SHC1	SHC (Src homology 2 domain containing) transforming protein 1
GSK3B	glycogen synthase kinase 3 beta	SOD1	superoxide dismutase 1, soluble
HSPA1A	heat shock 70kDa protein 1A	STAT3	signal transducer and activator of transcription 3 (acute-phase response factor)
HTRA2	HtrA serine peptidase 2	STK11	serine/threonine kinase 11
IGFBP3	insulin-like growth factor binding protein 3	TFAP2A	transcription factor AP-2 alpha (activating enhancer binding protein 2 alpha)
IL2	interleukin 2	TNF	tumor necrosis factor
IL2RG	interleukin 2 receptor, gamma	UBB	ubiquitin B
INS	insulin	UBE21	ubiquitin-conjugating enzyme E2I
INSR	insulin receptor	VEGFA	vascular endothelial growth factor A
M A PK8	mitogen-activated protein kinase 8	YWHAZ	tyrosine 3-monooxygenase/tryptophan 5-monooxygenase activation protein, zeta
MSRA	methionine sulfoxide reductase A

Running title: Plucked hair shafts-based epidermal aging

Abstract

Hair follicle (HF) is a unique system constituted of epithelial and mesenchymal compartments with the ability to cyclically regenerate during lifetime. Easy to be manipulated it represents an excellent model to study biological mechanisms, including aging. Follicular epidermis (the epidermal component of HF) is a tubular structure derivate from tissue invagination, continuous with the interfollicular epidermis (IFE). Despite constituting the same tissue, FE and IFE represent distinct biological niches with functional and morphological particularities, such as the presence of different stem-cell populations and expression of different types of keratins. As any other living tissue, epidermis suffers the effect of aging in all its extension, with cumulative deterioration and impaired homeostasis over the lifetime. Despite its critical role in the homeostasis maintenance, little is known about the aging of the human epidermis. In this work, we performed transcriptomic analyses of plucked hair shafts from a panel of 54 volunteer women of different ages to investigate the *in vivo* mechanisms of skin aging. These analyses revealed 3,039 probe sets (2,024 recognized HGNC mapped probe sets representing 1,945 distinct human genes), with 1,597 up-regulated and 1,442 down-regulated (fold change value of 1.5, p-value cut-off of 0.05). Hierarchical clustering showed a clear distinction between young and old groups with only three individuals of each group being not well classified. By comparing to the DAVID database, 33 gene ontology (GO) terms were associated with down-regulated gene expression, and 55 were associated with up-regulated gene expression. KEGG database comparisons identified thirty pathways with significant modulation (p-values cut-off: 0.01) Approximately 50% of these pathways are associated with human diseases and organismal systems, not necessarily related to skin. Interestingly, several significant pathways were related to signaling processes, such as the MAPK, chemokine, insulin, mTOR, Wnt, Notch and calcium signaling pathways. The results of this work were compared with those form our previous analysis of epidermal aging using tape stripping. The overall result of the comparison is quite surprising since both studies identified different biological processes and cellular

90
pathways. A total of 514 identified DEGs were common to the two studies, indicating a certain degree of similarity but with considerable differences between the materials. In summary, our results it indicate that IE and FE must be analyzed and interpreted as distinct epidermal niches, not just in relation to morphological localization, but also regarding molecular control.

Introduction

Hair follicle (HF) is a complex and unique system with the ability to cyclically regenerate during lifetime, representing an excellent, easily manipulated and widely available model to the study of many biological mechanisms, including aging (Rompolas *et al.*, 2012; Keyes *et al.*, 2013). Most research is focused on the comprehension of HF cycling control because of the great clinical interest associated to hair loss or unwanted hair growth (Krause and Foitzik, 2006). Furthermore, special attention has been done to hair graying with age, mainly due to its aesthetical impact and the interest of cosmetic industry (Tobin, 2009; Trüeb, 2005). However, potential application of HF in the studies of aging might not be restricted to the analysis of hair specific modifications. As a cutaneous appendage, HF is constituted of epithelial and mesenchymal compartments, undergoing changes throughout life that could reflect or complement aspects of overall skin aging (Keyes *et al.*, 2013).

Follicular epidermis (FE) – the epidermal component of HF – is a tubular structure derivate from tissue invagination, continuous with the interfollicular epidermis (IFE). Despite constituting the same tissue, FE and IFE represent distinct biological niches with functional and morphological particularities, such as the presence of different stem-cell populations and the expression of different types of keratin (Jiang *et al.*, 2010; Mascré *et al.*, 2012; Schweizer *et al.*, 2007). IFE is responsible for skin barrier function against dehydration and external damage, composed of an inner basal layer of proliferative cells and suprabasal layers of differentiating progeny; while FE is responsible for hair fibers formation, with concentric layers of cells originated by proliferation activity at the base of HF (Blanpain and Fuchs, 2009). In case of damage to skin, HF stem cells can totally regenerate IFE, indicating the maintenance of a general epidermal programming (Ito *et al.*, 2005; Solanas and Benitah, 2013).

As any other living tissue, epidermis suffers the effect of aging in all its extension, with cumulative deterioration and impaired homeostasis over a lifetime (Kirkwood, 2005). Despite its critical role in the homeostasis maintenance, little is

92

known about the aging of the human epidermis. We have previously performed a study focused on transcriptomic analysis using a non-invasive technique to access IFE aging (Lorencini *et al.*, unpublished results). The use of global techniques of analysis has been growing massively in the last years and the term skinomics has emerged as a tendency in the field of dermatology (Blumenberg, 2005). Since the skin represents a complex organ, some groups have been working with isolated skin layers or cells to achieve comprehensive results without traces of confounding material (Jansen and Schalkwijk, 2003; Mitsui *et al.*, 2012).

The plucked hair shaft has been used in medical research over the last 60 years (Schembri *et al.*, 2013), and gene expression studies have been done on such experimental model for many different purposes, such as the analysis of atopic dermatitis, stem cell behavior and hair cycle evaluation (Kim *et al.*, 2006; Ohyama *et al.*, 2006, Yoshikawa *et al.*, 2013). Moreover, plucked hair represents an *in vivo* alternative that can be sampled easily without a major discomfort to the individual participating in the research with minimal (if not absent) harm potential (Schembri *et al.*, 2013). Gho *et al.* (2004) demonstrated that typical break of mechanical plucking is located conically surrounding the dermal papilla, which remains unaffected inside the skin. Most of the HF epithelial structures remain attached to the plucked hair and only the epidermal constituents are involved in ~90% of the cases (Bassukas and Horstein, 1989). Thus, the use of plucked hair shafts suggests a powerful tool with unprecedented application (except from hair graying analysis, of course) to the study of FE aging.

This study aimed to elucidate *in vivo* mechanisms of skin aging by applying the non-invasive plucked hair shafts collection from the eyebrows and a global analysis of transcriptome with DNA microarrays. It represents an innovative and relevant approach in the molecular evaluation of human epidermal aging, contributing to the expansion of dermatology knowledge in the era of skinomics.

Material and methods

Volunteers and samples

The Research Ethics Committee institutional review board from Universidade Positivo, Curitiba, Brazil, approved this study, and written informed consent was obtained before enrolling volunteers for participation in this study, which was performed in compliance with the Declaration of Helsinki Principles. Plucked hair shafts were obtained from the eyebrows of women of different ages and skin phototype II or III according to the Fitzpatrick scale. Twenty HFs were collected from the left and right sides of each volunteer. Samples from 54 healthy women were used for microarray analysis (Table S1), and an independent panel of 22 healthy women was used for real-time qPCR validation (Table S3).

RNA extraction and processing

RNA extraction was performed using the RNeasy Mini Kit (Qiagen, Hilden, Germany). Hair follicles were agitated in Tissuelyser LT (Qiagen) for 5 minutes at 50 Hz with lysis buffer and two 7-mm magnetic beads (Qiagen), followed by the subsequent steps for total RNA extraction. Purified RNAs were quantified with a 2000c NanoDrop spectrometer (Thermo Scientific, Wilmington, NC, USA), and the quality was checked using a 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA, USA) and a Agilent RNA 6000 Pico Kit (Agilent Technologies). Because of the low total RNA yields, the samples were amplified with the Arcturus RiboAmp PLUS HS Kit (Applied Biosystems) and SuperScript III Reverse Transcriptase (Applied Biosystems). All procedures were performed according to manufacturers' instructions.

RNA labeling, hybridization and microarray scanning

Amplified RNAs were processed using the Turbo Arcturus Labelling Kit (Applied Biosystems), and samples were labeled with Cy5. Universal Human Reference RNA (Agilent Technologies) from a unique batch was labeled with Cy3 for use in the data normalization of different arrays (Novoradovskaya *et al.*, 2004).

The use of exogenous RNA from the Agilent RNA Spike-in Kit (Agilent Technologies) was also used for the further calibration of the microarray measurements (Yang, 2006). After fragmentation with the Gene Expression Hybridization Kit (Agilent Technologies), 1:1 ratio mixtures of Cy5-labeled RNA from each volunteer and Cy3-labeled Universal Human Reference RNA (Agilent Technologies) were co-hybridized to two-color Agilent Whole Human Genome Oligo 44K microarrays (Agilent Technologies) to evaluate ~44,000 probe sets, which target 19,596 genes. Scanning and image analysis were performed using the Agilent DNA Microarray Scanner (Agilent Technologies). All procedures were performed according to manufacturers' instructions.

cDNA synthesis and real-time qPCR

To validate the gene expression patterns in the RNA samples, cDNA was obtained using a ReverAid First Strand cDNA Synthesis Kit (Thermo Scientific). cDNA from three or four volunteers in the same age group was pooled in equal quantities, resulting in three samples for analysis for each group (young and old), and real-time qPCR was performed in duplicate for each sample using the ViiA 7 Real Time PCR System (Applied Biosystems) with the TagMan Fast Advanced Master Mix (Applied Biosystems) and TagMan Gene Expression Assays (Applied Biosystems) for the following target genes: aquaporin 9 (AQP9, Hs01035888 m1); caveolin 1 (CAV1, Hs00971716 m1); CCAAT/enhancer binding protein, alpha (CEBPA, Hs00269972 s1); collagen, type XXVII, alpha 1 (COL27A1, collagen, type XXVII, alpha 1); D site of albumin promoter (albumin D-box) binding protein (DBP, Hs00609747 m1); fibroblast growth factor receptor 1 (FGFR1, Hs00915142 m1); forkhead box Q1 (FOXQ1, Hs00536425 s1); heme oxygenase (decycling) 2 (HMOX, Hs01558390 m1); interleukin 10 receptor, alpha (IL10RA, Hs00155485 m1); and procollagen-lysine, 2-oxoglutarate 5-dioxygenase 3 Hs01126617 m1). (ACTB, Hs9999903 m1) (PLOD3, Beta actin and glyceraldehyde-3-phosphate dehydrogenase (GAPDH, Hs03929097 g1) were

95

used as endogenous controls. All procedures were performed according to manufacturers' instructions.

Data analysis

Microarray raw data were extracted using the Agilent Feature Extraction v8.1 software (Agilent Technologies, Santa Clara, CA, USA). Data visualization and analysis were performed using the GeneSpring v12.5 software (Agilent Technologies). Data normalization was performed within and across the arrays using per gene, per chip normalization, according to Agilent's recommendation. To detect the differentially expressed genes (DEGs) between experimental conditions, unpaired t-test was performed with a p-value cut-off of 0.05, considering the minimal fold change (FC) of 1.5. Hierarchical clustering was performed using the Euclidean distance metric and Average rule. For real-time qPCR experiments, the FC was calculated using the ddCt technique (Livak and Schmittgen, 2001). The DAVID database was used to conduct functional enrichment analysis (Huang et al., 2009a and 2009b). The human genome was used as a reference, and regulated GO terms were ranked according to their p-values (or called EASE score, a modified Fisher's exact test) with a cut-off of 0.01; Benjamini correction was also considered for ranking but not elimination (<u>www.david.abcc.ncifcrf.gov</u>). The KEGG database was used for the analysis of modulated pathways (Kanehisa and Goto, 2000; Kanehisa et al., 2014), considering the human genome as a reference and an adjusted p-value cut-off of 0.01 (www.genome.jp/kegg).

Results

Panel of volunteers and sample considerations

We recruited a panel of volunteers comprising 54 women who were distributed into two groups of age i.e., 30 ± 8 years old (30 volunteers) and 64 ± 13 years old (24 volunteers) (Table S1). Using non-invasive eyebrow plucked hair

shafts collection, our analysis focused on FE. Most of the epidermal material of the HF remains attached to the plucked hair and only the epidermal constituents are involved in ~90% of the cases, with no contaminant dermal material (Bassukas and Horstein, 1989).

Microarray analysis and technical validation using real-time qPCR

By adopting a minimal fold change (FC) value of 1.5 and a p-value cut-off of 0.05, statistically significant differences were observed for 3,039 probe sets (2,024 recognized HGNC mapped probe sets representing 1,945 distinct human genes), with 1,597 up-regulated and 1,442 down-regulated (Table S2). Technical validation of the microarray results was performed using real-time qPCR in an independent young versus old panel including 12 volunteers who were 25 ± 3 years old and 10 volunteers who were 54 ± 2 years old (Table S3). Similar results were found for the expression of 10 randomly selected genes (up-, down- or non-regulated) (Figure 1).

Figure 1. Real-time qPCR validation of microarray results. These qPCR results represent the median (\pm SD) of triplicate analyses using an independent secondary panel of volunteers (12 young, 10 old). GAPDH and ACTB were used as endogenous controls. A complete list of regulated genes can be found in Table S2.

A hierarchical clustering analysis was performed with the independent and consistently detected data of all volunteers, filtered according to a p-value cut-off of 0.05. A clear distinction between pre-defined groups of young and old volunteers was observed with only three individuals of each group that were not well classified (Figure 2).

Figure 2. Hierarchical clustering analysis of the complete panel of independent volunteers. Spontaneous hierarchical clustering evidenced that young and old groups defined were quite homogeneous. The ages in red, at the right side, indicate few volunteers that were not classified as expected *a priori*.

Separate lists of the up- and down-regulated genes (Table S2) were analyzed in the DAVID database to identify significantly up- and down-modulated biological processes, respectively, ranked according to p-value (cut-off 0.01) (Table 1). 33 gene ontology (GO) terms were associated with down-regulated gene expression, and 55 were associated with up-regulated gene expression. However, it is important to note that, among the up-regulated GO, many have the description "negative regulation of", which can reverse our interpretation of that result.

1. DEGs, differentially expressed genes.

To identify the modulated pathways, the complete list of modulated genes was analyzed using the KEGG database (Table S2). Thirty pathways showed significant modulation and were ranked according to their p-values (cut-off: 0.01) (Table S4). In addition to statistical significance, biological interpretation is essential for meaningful pathway analysis. Of the identified pathways, ~50% were associated with human diseases and organismal systems not necessarily related to skin. Interestingly, several significant pathways were related to signaling processes, such as the MAPK, chemokine, insulin, mTOR, Wnt, Notch and calcium signaling pathways.

The results of this work were compared with those form our previous analysis of epidermal aging using tape stripping (Lorencini *et al.*, unpublished results). A total of 514 identified DEGs were common to the two studies (Figure 3), indicating a certain degree of similarity but with considerable differences between the materials.

Figure 3. Comparison of gene expression modulation with aging in tape strip and plucked hair shaft. Numbers inside the circles represent the amount of differentially expressed genes (DEGs) observed in the young versus old comparison in the correspondent biological material.

Discussion

In this work, the analysis of aging was established by comparing adult women from two groups of age, representing the most common approach used by other groups in this field. Since menopause characterizes a typical age-associated systemic change with great impact on skin (Raine-Fenning *et al.*; 2003), it was adopted for the definition of young and old groups. Furthermore, spontaneous hierarchical clustering evidenced that pre- and post-menopause groups defined *a priori* were quite homogeneous, reinforcing the biological significance of our experimental approach. The epidermal material from plucked hair shaft demonstrated a better performance for the correct segregation of young versus old material in comparison to the use of tape strip (data not shown). These findings substantiate our choice and refuse any arbitrary decision, before continuing with global data analysis.

The analysis of regulated GO terms in HF showed interesting results, but difficult to correlate with clinical or morphological aspects of epidermal aging. In fact, it was observed a prevalence of broad spectrum terms, such as cellular, metabolic or biosynthetic processes, and gene expression or transcription. In the up-regulated list, the same processes appear more than once and sometimes are preceded by the expression "negative regulation of". It suggests that even the upregulation associated with aging, which would be erroneous related to the interpretation of higher cellular metabolic activity, is linked to an inhibitory effect on those biological processes. Regarding the down-regulated GO terms, the processes of signal transduction and development were the most significant ones. Moreover, modulation of several signaling pathways was the most remarkable characteristic of aging in our results with HF, including several key genes such as an extensive representation of zinc finger proteins and associated elements (~70 related DEGs).

Accordingly to a recent work by Tevy *et al.* (2013), for unknown reasons, there is a decline in circadian rhythms with age, concomitant with declines in the overall metabolic tissue homeostasis. The timing of stem cells proliferation and differentiation in the epidermis of the HF occurs in a controlled manner through circadian rhythm. In a mice model presenting disturbed circadian rhythm, the epidermis is prematurely aged and predisposed to tumorigenesis (Janich *et al.*, 2011). So, considering all the findings of deregulated signaling transduction, our results might provide a link between disturbed circadian rhythm and the impaired regulation of stem cells behavior in the epidermal HF with age. Several other mechanistic and corroborative analyses could be further performed to understand which factor is causing or being caused by a wide impairment in cellular epidermal signaling.

The comparison of the HF results with that derived from tape indicates that, despite some similarities in gene expression, the two biological materials display very distinct profiles in the processes affected by aging. While tape analysis showed several processes associated to epidermal differentiation and keratinocytes regulation, results from HF indicated absolutely broader pathways, which is much more coherent to a tissue enriched in heterogeneous undifferentiated cells (Solanas *et al.*, 2013). Clearly, our results indicate that IE and FE must be analyzed and interpreted as distinct epidermal niches, not just in relation to morphological localization, but also regarding molecular control.

In conclusion, the use of plucked hair shaft represents a useful tool for the study of skin aging and, in particular, for the evaluation of age-related changes in

103

the FE. We have used eyebrow HF in our study, which can be a good alternative to study age-related changes in the face and could be a good tool for analyzing the effects of anti-aging products that are applied on the face.

Symbol ¹				Symbol ¹			
37469	argonaute RISC catalytic component 2	2,09	up	APBA3	A. member 3	1,83	down
AAAS	achalasia, adrenocortical insufficiency, alacrimia	1,53	down	APH1B	APH1B gamma secretase subunit	1,76	up
AARS	alanyl-tRNA synthetase	1,53	up	APLP2	amyloid beta (A4) precursor-like protein 2	1,55	up
ABCB10	ATP-binding cassette, sub-family B (MDR/TAP), member 10	1,62	up	APOA1	apolipoprotein A-I	1,50	down
ABCC6	ATP-binding cassette, sub-family C (CFTR/M RP), member 6	1,91	up	APOBEC3B	apolipoprotein B mRNA editing enzyme, catalytic polypeptide-like 3B	1,64	down
ABCC8	ATP-binding cassette, sub-family C (CFTR/MRP), member 8	1,81	down	APOC1	apolipoprotein C-I	1,56	up
ABCD1	ATP-binding cassette sub-family D (ALD) member 1	164	10	APOL3	apolipoprotein L 3	2 11	down
ABCE1	ATP-binding cassette, sub-family E (OABP), member 1	2,09	up	APOPT1	apoptogenic 1, mitochondrial	1,96	up
ABHD1	abhydrolase domain containing 1	1.55	up	APPBP2	amyloid beta precursor protein (cytoplasmic tail)	1.92	up
ABHD10	abbydrolase domain containing 10	186		AOP2	binding protein 2 aquaporin 2 (collecting duct)	173	down
ABHD11	abhydrolase domain containing 10	1,67	up	AQP9	aquaporin 9	1,81	up
ABHD16B	abhydrolase domain containing 16B	2,14	down	ARF1	ADP-ribosylation factor 1	2,06	up
ABI3	ABI family, member 3	1,78	down	ARHGAP27	Rho GTPase activating protein 27	1,96	down
ABTB1	ankvrin repeat and BTB (POZ) domain containing 1	1.53	down	ARHGEF17	Rho guanine nucleotide exchange factor (GEF) 17	1.52	down
ACAD10	acyl-CoA dehydrogenase family, member 10	1,93	down	ARHGEF25	Rho guanine nucleotide exchange factor (GEF) 25	1,68	down
ACAN	aggrecan	1,50	up	ARHGEF3	Rho guanine nucleotide exchange factor (GEF) 3	1,73	up
ACBD3	acetyl-CoA acetyltransferase 2 acyl-CoA binding domain containing 3	1,62	up	ARHGEF38	Bho quarine nucleotide exchange factor (GEF) 58	2,42	up
ACBD4	acyl-CoA binding domain containing 4	1,56	down	ARID 1A	AT rich interactive domain 1A (SWI-like)	1,88	up
ACOT13	acyl-CoA thioesterase 13	1,88	up	ARID1B	AT rich interactive domain 1B (SWI1-like)	3,24	down
ACP2	acid phosphatase 2, lysosomal	1,64	down	A RI 17B	A Frich Interactive domain 5B (MHF1-like)	1,58	down
ACSM3	acyl-CoA synthetase medium-chain family member 3	1,81	up	ARL3	ADP-ribosylation factor-like 3	2,28	up
ACSM 5	acyl-CoA synthetase medium-chain family member 5	6,14	down	ARL6IP1	ADP-ribosylation factor-like 6 interacting protein 1	1,79	up
ACSS1	acyl-CoA synthetase short-chain family member 1	1,67	down	ARRDC1	arrestin domain containing 1	1,52	up
AG1N4	actinin, alpha 4 ABP1 actin-related protein 1 homolog B. centractin beta	1,78	down	ARRDG2	arrestin domain containing 2	1,70	up
ACTR1B	(yeast)	1,94	down	ARSG	arylsultatase G	1,50	up
ACTR3	ARP3 actin-related protein 3 homolog (yeast)	1,73	up	ARVCF	syndrome	1,82	down
ACVR2B	activin A receptor, type IIB	1,83	down	ARX	aristaless related homeobox	2,65	down
ADAD1	adenosine deaminase domain containing 1 (testis-specific)	1,54	down	ASD IS ASCI 2	achaete-scute family bHI Htranscription factor 2	2,01	up
ADAM 17	ADAM metallopeptidase domain 17	1,86	up	ASPA	asparto acylase	1,64	down
ADAM 21	ADAM metallopeptidase domain 21	1,55	down	ASPHD2	aspartate beta-hydroxylase domain containing 2	1,97	down
ADAMTS4	ADAM metallopeptidase with thrombospondin type 1 motif, 4	2,08	down	ASRGL1	asparaginase like 1	1,52	down
ADAM TSL1	ADAMTS-like 1	1,71	up	ASTL	astacin-like metallo-endopeptidase (M 12 family)	1,74	down
ADAM ISL2	ADAM I S-like 2 ademulate cyclase 3	1,53	down	ASXL2	additional sex combs like 2 (Drosophila)	1,70	down
ADD3	adducin 3 (gamma)	1,64	down	ATCAY	ataxia, cerebellar, Cayman type	4,80	down
ADI1	acireductone dioxygenase 1	1,81	up	ATG16L1	autophagy related 16-like 1 (S. cerevisiae)	1,85	up
ADM	adrenomedullin	1,51	down	ATG4A	autophagy related 4A, cysteine peptidase	3,06	down
ADORA3	adenosine A3 receptor adenosine A3 receptor	2,05	down	ATG7	autophagy related 4D, cysteine peptidase autophagy related 7	1,98	up
ADPGK	ADP-dependent glucokinase	1,57	up	ATN1	atrophin 1	1,53	down
ADRA2A	adrenoceptor alpha 2A	2,46	down	ATOH7	atonal homolog 7 (Drosophila)	2,53	down
ADRA2B	adrenoceptor alpha 2B adrenargic beta recentor kinase 2	2,08	down	ATOH8	atonal homolog 8 (Drosophila)	1,52	down
AES	amino-terminal enhancer of split	2,21	up	ATP1B1	ATPase, Na+/K+ transporting, beta 1 polypeptide	2,43	up
AFG3L1P	AFG3-like AAA ATPase 1, pseudogene	2,16	up	ATP5E	ATP synthase, H+ transporting, mitochondrial F1	1,77	up
AGPAT3	1-acylglycerol-3-phosphate O-acyltransferase 3	1,52	up	ATP5J2	ATP synthase, H+ transporting, mitochondrial Fo	2,08	up
AGPAT4	1-acylglycerol-3-phosphate O-acyltransferase 4	1,87	down	ATP6V1A	ATPase, H+ transporting, lysosomal 70kDa, V1	1,67	up
AGR2	anterior gradient 2	2,65	up	ATP6V1C2	ATPase, H+ transporting, lysosomal 42kDa, V1	3.83	down
AHCTE1	AT book containing transcription factor 1	172	UD	A TP6V 1G2	subunit C2 ATPase, H+ transporting, lysosomal 13kDa, V1 subunit	177	un
		0.01	49	ATD901	G2 ATPase, aminophospholipid transporter, class I, type	179	down
ALINAN		2,21	up	ATFORT	8B, member 1 ATP synthase mitochondrial F1 complex assembly	1,73	
AK1	adenylate kinase 1	2,05	up	A I PAF1	factor 1	1,54	down
AKAP17A	A kinase (PRKA) anchor protein 17A	1,69	down	ATRNL1	attractin-like 1	1,82	down
ALDH4A1	aldehvde dehvdrogenase 4 family, member A1	3.08	down	ATXIN/L3 AXIN1	ataxin 7-like 3 axin 1	1,53	down
ALKBH5	alkB, alkylation repair homolog 5 (E. coli)	1,79	down	AZIN1	antizyme inhibitor 1	1,57	up
ALOX 12B	arachidonate 12-lipoxygenase, 12R type	1,74	down	B3GALNT1	beta-1,3-N-acetylgalactosaminyltransferase 1	1,60	up
ALOX 15	arachidonate 15-linoxygenase	2.17	down	B3GAT2	(globoside blood group) beta-1,3-glucuronyltransferase 2	169	up
ALOX 54 P	arachidonate 5-linoxygenase-activating protein	2.28	down	B4GALT1	(glucuronosyltransferase S) UDP-Gal:betaGlcNAc beta 1,4- galactosyltransferase,	183	un.
ALDI	alkoline phosphotoco, liver/hono/kidpov	167	down	PANC	polypeptide 1	107	up
ALYREF	Aly/REF export factor	1,91	down	BAG3	BCL2-associated athanogene 3	1,57	up
AMD1	adenosylmethionine decarboxylase 1	3,50	down	BAI3	brain-specific angiogenesis inhibitor 3	1,61	up
AM DHD1	amidohydrolase domain containing 1	1,85	up	BAP1	BRCA1 associated protein-1 (ubiquitin carboxy- terminal hydrolase)	1,60	up
AM ER3	APC membrane recruitment protein 3	1.81	down	BATF3	basic leucine zipper transcription factor. ATF-like 3	1.51	down
AMH	anti-Mullerian hormone	2,57	down	BAZ2A	bromodomain adjacent to zinc finger domain, 2A	1,63	down
AMZ2	archaelysin family metallopeptidase 2	1,75	up	BBC3	BCL2 binding component 3	2,41	up
ANG ANGEL2	angrogenin, noonuclease, mixase A family, 5 angel homolog 2 (Drosophila)	1,70	up up	BBS4	Bardet-Biedi syndrome 4	1,62 1,52	up down
ANK1	ankyrin 1, erythrocytic	1,76	down	BCAM	basal cell adhesion molecule (Lutheran blood group)	1,99	up
ANKFY1	ankyrin repeat and FYVE domain containing 1	1,58	up	BCAN	brevican	1,88	down
ANKHD1	ankyrin repeat and KH domain containing 1	1,59	up	BCAP29	B-cell receptor-associated protein 29 breast carrinoma amplified accurace 2	1,57	up
ANKRD12	ankyrin repeat domain 12	2,45 2,28	up up	BCASS	branched chain ketoacid dehvdrogenase kinase	1,79	up
ANKRD13B	ankyrin repeat domain 13B	1,52	down	BCL7A	B-cell CLL/lymphoma 7A	1,57	down
ANKRD2	ankyrin repeat domain 2 (stretch responsive muscle)	1,52	down	BCL7C	B-cell CLL/lymphoma 7C	1,60	up
ANXA2	annexin A2 annexin A2	d,/0 3,02	up	BCM 01	beta-carotene 15,15'-monooxygenase 1 brain-enriched quanylate kinase-accociated	1,66 1,87	up
ANXA2P1	annexin A2 pseudogene 1	2,04	up	BET1	Bet1golgi vesicular membrane trafficking protein	1,50	down
ANXA6	annexin A6	2,34	up	BGN	biglycan	1,54	down
ANXA8	annexin A8 aldehvde oxidase 1	1,67 1.76	up	BHLHA 15	basic helix-loop-helix family, member a15	1,52	down
AP2A2	adaptor-related protein complex 2, alpha 2 subunit	1,66	up	BIN1	bridging integrator 1	1.53	down

BIRC7	baculoviral IAP repeat containing 7	1,69	down	CD300E	CD300e molecule	2,02	down
BLK	B lymphoid tyrosine kinase	1,73	down	CD300LB	CD300 molecule-like family member b	2,58	down
BNIP3L	BCL2/adenovirus E1B 19kDa interacting protein 3-like	2,20	up	CD3E	CD3e molecule, epsilon (CD3-TCR complex)	1,59	down
BOK	BCL2-related ovarian killer	1,86	down	CD96	CD96 molecule	1,63	down
BPIF BDAT1	BRCA1 associated ATM activator 1	1,95	up	CDC34	cell division cycle 34	2,20	down
BRIBRP	BBI3 binding protein	158	down	CDC42EP1	CDC42 effector protein (Bbo GTPase binding) 1	181	down
BRI3BP	BRI3 binding protein	1.91	up	CDC42EP5	CDC42 effector protein (Rho GTPase binding) 5	1.92	up
BRPF1	bromodomain and PHD finger containing, 1	1,55	up	CDH23	cadherin-related 23	1,53	down
BST2	bone marrow stromal cell antigen 2	1,51	down	CDH6	cadherin 6, type 2, K-cadherin (fetal kidney)	1,57	down
BTBD16	BTB (POZ) domain containing 16	1,89	up	CDH7	cadherin 7, type 2	2,89	down
BTBD3	BTB (POZ) domain containing 3	2,41	down	CDK9	cyclin-dependent kinase 9	1,58	up
BTBD7	BTB (POZ) domain containing 7	156	un	CDKN2B	cyclin-dependent kinase inhibitor 2B (p15, inhibits	190	down
01007	b rb (r oz) donan onkannig r	1,00	цþ	ODIVIED	CDK4)	1,00	
BTF3	basic transcription factor 3	1,98	up	CDX1	caudal type homeobox 1	1,54	down
BTG1	B-cell translocation gene 1, anti-proliferative	2,00	up	CEACAM 1	carcinoembryonic antigen-related cell adhesion	2,00	up
					molecule 1 (biliary glycoprotein)		
BTK	Bruton agammaglobulinemia tyrosine kinase	1,60	down	CEACAM 4	carcinoembryonic antigen-related cell adhesion	1,51	down
BTN2A2	huturonhilin cubfamily 2 member A 2	165	down	CERPA	CCAAT/ophancer binding protein (C/ERP) aloba	4.04	down
BUB3	BLIB3 mitotic checkpoint protein	156	un	CELSB2	cadherin EGELAG seven pass G-type recentor 2	181	un
BZW1	basic leucine zinner and W2 domains 1	155	up	CENPB	centromere protein B. 80kDa	151	down
BZW1	basic leucine zipper and W2 domains 1	1.52	up	CENPI	centro mere protein I	1.80	down
C11orf86	chromosome 11 open reading frame 86	1,73	down	CENPN	centromere protein N	1,51	down
C15orf 52	chromosome 15 open reading frame 52	1,54	up	CEP192	centrosomal protein 192kDa	1,54	up
C16orf92	chromosome 16 open reading frame 92	1,59	up	CES2	carboxylesterase 2	1,56	down
C19orf68	chromosome 19 open reading frame 68	2,05	down	CES2	carboxylesterase 2	2,26	up
C1GALT1	core 1 synthase, glycoprotein-N-acetylgalactosamine 3-beta-	2,04	down	CETN1	centrin, EF-hand protein, 1	1,52	down
	galactosyltransferase, 1				,		
C1GALT1C1	C1GALT1-specific chaperone 1	1,82	down	CHAC2	ChaC, cation transport regulator homolog 2 (E. coli)	1,70	up
C1QB	complement component 1, q subcomponent, B chain	1,58	down	CHCHD1	coiled-coil-helix-coiled-coil-helix domain containing 1	1,83	up
C1QTNF1	C1q and tumor necrosis factor related protein 1	1,94	down	CHCHD2	coiled-coil-helix-coiled-coil-helix domain containing 2	2,00	up
				0110110.0			
62	complement component 2	2,05	up	GHGHD2	colled-coll-helix-colled-coll-helix domain containing 2	1,84	up
C2CD4B	C2 calcium-dependent domain containing 4B	2,17	down	CHD9	chromodomain helicase DNA binding protein 9	1,62	up
C2orf80	chromosome 2 open reading frame 80	1,72	down	CHM P6	charged multivesicular body protein 6	2,74	down
C5AR1	complement component 5a receptor 1	1,60	up	CHRDL1	chordin-like 1	2,81	down
C5AR2	complement component 5a receptor 2	1,66	down	CHRNB1	cholinergic receptor, nicotinic, beta 1 (muscle)	1,62	up
C7orf62	chromosome 7 open reading frame 62	1.89	down	CHST1	carbohydrate (keratan sulfate Gal-6) sulfotransferase	1.54	down
					1		
CBA	complement component 8, alpha polypeptide	1,66	up	CHST10	carbohydrate sulfotransferase 10	1,63	down
CA6	carbonic annydrase VI	2,24	up	CHST12	carbohydrate (chondroitin 4) sulfotransferase 12	2,27	up
CABIN1	calcineurin binding protein 1	1,66	up	CHST 14	cultotrapeforace 14	1,97	down
					Surotransierase in		
CABP1	calcium binding protein 1	1,61	down	CIDECP	cell death-inducing DFFA-like effector c pseudogene	1,74	up
CACNA1B	calcium channel, voltage-dependent, N type, alpha 1B subunit	2,16	down	CIRBP	cold inducible RNA binding protein	1,98	down
CACNATE	coloium channel upitage dae andert I tupe, alebe 15 suburit	161	down	CKADA	autopholotop oppopiated protoio 4	2.04	
GAGNAIF	calcium chamer, von age-dependent, Litype, alpha in subunit	1,01	down	GNAF4	Cytoskeleton-associated protein+	2,04	up
CACNG1	calcium channel, voltage-dependent, gamma subunit 1	1,61	down	CLCF1	cardiotrophin-like cytokine factor 1	2,01	down
CACNG7	calcium channel, voltage-dependent, gamma subunit 7	1,94	down	CLCN3	chloride channel, voltage-sensitive 3	1,51	up
CACNG8	calcium channel, voltage-dependent, gamma subunit 8	2,45	down	CLDN1	claudin 1	1,95	up
CACYBP	calcyclin binding protein	1,82	up	CLDN9	claudin 9	3,94	down
CACYBP	calcyclin binding protein	1,57	up	GLDN9	claudin 9	1,66	down
CALDI	caldesmon 1	1,92	up	CLEC4A	C-type lectin domain ramity 4, member A	1,76	down
CALDI	caldeshorn i	1,00	dawa	CLID4	chionae intracenaria channer 4	2,01	up
GALMED	camodumentes	1,93	down	GLINTT	CAP-CLV domain containing linker protein family	1,94	up
CALR3	calreticulin 3	1,88	up	CLIP4	member 4	1,57	up
CAMK2N1	calcium/calmodulin-dependent protein kinase II inhibitor 1	2.25	up	CLPB	ClpB caseinolytic peptidase B homolog (E. coli)	1.53	up
041404.00	calmodulin regulated spectrin-associated protein family,	470		OLDTMA		0.07

PHF2	PHD finger protein 2	1,61	up		PRSS42	protease, serine, 42	1,63
PHF20	PHD finger protein 20	1,51	down		PRSS53	protease, serine, 53	1,60
PHIP	pleckstrin homology domain interacting protein	1,62	up		PSD3	pleckstrin and Sec7 domain containing 3	1,56
PHKA2	phosphorylase kinase, alpha 2 (liver)	1,61	up		PSM C2	proteasome (prosome, macropain) 26S subunit,	1,87
						A I Pase, 2	
PHKB	phosphorylase kinase, bet a	1,65	up		PSM C5	ATPaco 5	1,51
						A Frase, 5 protoscomo (procomo macropain) accombly	
PHLDA1	pleckstrin homology-like domain, family A, member 1	1,71	down		PSM G2	chaperone 2	1,88
					BOTOLO -	proline-serine-threenine phosphatase interacting	
PIAS2	protein inhibitor of activated STA1, 2	1,54	up		PSTPIP1	protein 1	3,00
PID 1	phoephotyroging interaction domain containing 1	1.61	10		DTA D1	protein prenyltransferase alpha subunit repeat	195
TID1	prosphotyrosine interaction domain containing i	1,01	up		11000	containing 1	1,00
PIGG	phosphatidylinositol glycan anchor biosynthesis, class G	1,58	up		PTBP3	polypyrimidine tract binding protein 3	2,92
PIGG	phosphatidylinositol glycan anchor biosynthesis, class G	1,54	up		PTCH2	patched 2	1,98
PIGT	phosphatidylinositol glycan anchor biosynthesis, class T	1,85	up		PTCRA	pre T-cell antigen receptor alpha	1,73
PIGT	phosphatidylinositol giycan anchor biosynthesis, class Y	1,66	up		P10552	phosphatid viserine synthase 2	1,73
PIK3CD	phosphatoyinositor-4,5-bisphosphate 5-kinase, catalytic	1,65	down		PTEN	phosphatase and tensin homolog	1,79
PIK3 IP1	phosphoinositide.3-kinase interacting protein 1	153	down		PTODR	prostaglandin D2 recentor (DP)	2.01
PIK3 IP1	phosphoinositide-3-kinase interacting protein 1	1,55	up		PTGER4	prostaglandin E receptor 4 (subtype EP4)	1,53
DINHDI	peptidylprolyl cis/trans isomerase, NIM A-interacting 1	104	daum		DTOESS	n restantendin E sunthese 2 (sute solis)	150
FINIFI	pseudogene 1	1,94	down		FIGESS	prostagranum E synthase 3 (cytosonic)	1,32
PIN1P1	peptidylprolyl cis/trans isomerase, NIM A-interacting 1	1.80	up		PTMA	prothymosin, alpha	1.94
	pseudogene 1	.,					
PIP5K1A	phosphatidylinositol-4-phosphate 5-kinase, type I, alpha	1,51	up		PTMA	prothymosin, alpha	1,67
PITPINGT	phosphatidylinositol transfer protein, cytoplasmic 1	1,62	down		PIN	pielotrophin	2,19
PRDILZ	polycystic kidney disease Filke 2	1,01	down		FIFDGI	protein tyrosine phosphatase like A domain	1,60
PKD2L1	polycystic kidney disease 2-like 1	1,61	down		PTPLAD2	containing 2	1,55
PKD2L2	polycystic kidney disease 2-like 2	161	up		PTPN11	protein tyrosine phosphatase non-recentor type 11	1.59
PKP2	plakophilin 2	1,70	up		PTPN2	protein tyrosine phosphatase, non-receptor type 2	1,69
DIACOS	nhaanhalingee AQ, graym XV/I	174	dauna		DTDNE	protein tyrosine phosphatase, non-receptor type 5	150
FLA2GID	prosprolipase A2, group A vi	1,74	down		FIFNS	(striatum-enriched)	1,32
PLA2G2F	phospholipase A2, group IIF	1,56	down		PTPRH	protein tyrosine phosphatase, receptor type, H	1,58
PLAC1	placenta-specific 1	1,87	up		PUM2	pumilio RNA-binding family member 2	1,84
PLCB2	phospholipase C, beta 2	1,61	up		PVALB	parvalbumin	1,99
PLD1	phospholipase D1, phosphatidylcholine-specific	1,99	up		PVRL2	poliovirus receptor-related 2 (herpesvirus entry	1,88
	placketrin homology domain containing family A member 6	2.51	down		PVCPI	mediator B)	169
FLENNAG	pleckstrin homology domain containing, family A member 6	2,31	down		FTORE	pyrrolline-o-carboxylatereductase-like	1,00
PLEKHF1	domain) member 1	1,87	down		PYDC1	PYD (pyrin domain) containing 1	1,51
	pleckstrin homology domain containing, family G (with						
PLEKHG4B	RhoGef domain) member 4B	1,66	down		PYGB	phosphorylase, glycogen; brain	1,98
DI EKUM 1D	pleckstrin homology domain containing, family M (with RUN	2.64	down		PV CO1	pygopus family PHD finger 1	1.59
FLENHW IF	domain) member 1 pseudogene	2,34	down		FIGO	pygopus ranny PhD ringer r	1,30
PLIN3	perilipin 3	1,75	up		QPRT	quinolinatephosphoribosyltransferase	2,03
PLIN4	perilipin 4	1,53	down		QSOX2	quiescin Q6 sulfhydryl oxidase 2	1,63
PLK2	polo-like kinase 2	2,00	up		R3HDM 2	R3H domain containing 2	1,97
PLOD3	procollagen-lysine, 2-oxoglutarate 5-dioxygenase 3	2,50	down		RAB22A	RAB22A, member RAS oncogene family RAB2A, member RAS oncogene family	2,12
PIXNA4	plexin domain containing 2	164	up		RAB36	RAB36 member RAS oncogene family	162
PLXND1	plexin D1	1,04	down		BAB3D	BAB3D member BAS oncogene family	175
PM20D1	peptidase M 20 domain containing 1	1.51	down		RAB42	RAB42, member RAS oncogene family	1.75
PM EPA1	prostate transmembrane protein, androgen induced 1	1,86	down		RAB43	RAB43, member RAS oncogene family	1,58
PM FB P1	polyamine modulated factor 1 binding protein 1	1,69	up		RAB4B	RAB4B, member RAS oncogene family	1,50
PM P2	peripheral myelin protein 2	2,05	down		RAB7B	RAB7B, member RAS oncogene family	1,79
PM P22	peripheral myelin protein 22	2,29	up		RABGAP1	RAB GTPase activating protein 1	1,52
PNKD	paroxysmal nonkinesigenic dyskinesia	1,59	up		RABGEF1	RAB guanine nucleotide exchange factor (GEF) 1	1,55
PNM A3	paraneoplastic M a antigen 3	1,60	down		RABIF	RAB interacting factor	1,80
PNM A6A	paraneoplastic M a antigen family member 6A	1,/1	down		RABL6	RAB, member RAS oncogene family-like 6	2,49
PNMALI	paraneoplastic M a antigen family-like 1	2,08	down		RAD23B	RAD23 nomblog B (S. cerevisiae)	1,53
POC14	POC1 centricial a protein A	1,00	down		RAII	retinoic acid induced 1	1,00
POLA1	polymerase (DNA directed) alpha 1 catalytic subunit	1.51	un		BANBP2	BAN binding protein 2	1.58
POLD2	polymerase (DNA directed), delta 2, accessory subunit	1,55	down		RANBP3	RAN binding protein 3	1,69
POLE2	polymerase (DNA directed), epsilon 2, accessory subunit	2,30	down		RAPGEF1	Rap guanine nucleotide exchange factor (GEF) 1	1,73
POLE3	polymerase (DNA directed) ensiton 3 accessory subunit	2 34	un		RARRES2	retinoic acid receptor responder (tazarotene induced)	154
10220	portification (Drive an excess), oponorro, accessory subunit	2,04	цр		TO THE DE	2	1,01
POLL	polymerase (DNA directed), lambda	1,68	down		RASGEF1A	RasGEF domain family, member 1A	1,55
POLQ	polymerase (DNA directed), theta	1,70	down		RASGEF1C	RasGEF domain family, member 1C	1,87
POLR 1C	polymerase (RNA) I polypeptide C, 30kDa	1,54	up		RASGRP2	RAS guanyl releasing protein 2 (calcium and DAG-	1,61
						regulated)	
POLR2B	polymerase (RNA) II (DNA directed) polypeptide B, 140kDa	1,81	up		RASGRP4	RAS guanyl releasing protein 4	1,62
PON3	paraoxonase 3	2 10	up		BAX2	retina and anterior neural fold homeobox 2	2.09
POU5F1	POU class 5 homeobox 1	1.51	up		RBBP4	retinoblastoma binding protein 4	3.09
PPAN	peter pan homolog (Drosophila)	1,68	down		RBM 15B	RNA binding motif protein 15B	1,74
PPCS	phosphopantothenoylcysteine synthetase	1,56	up		RBM 17	RNA binding motif protein 17	2,20
PPFIA1	protein tyrosine phosphatase, receptor type, f polypeptide	157	down		BBM 17	BNA binding motif protein 17	157
	(PTPRF), interacting protein (liprin), alpha 1	.,					.,
PPFIA4	protein tyrosine phosphatase, receptor type, t polypeptide	1,66	down		RBM28	RNA binding motif protein 28	1,76
DDIA	(FTFRF), Interacting protein (lipini), apria 4	150	10		DBM20	RNA binding motif protoin 29	162
PPIAI 44	peptidylprolyl isomerase A (cyclophilli A)-like 4 A	2,05	up un		BBM41	RNA binding motif protein 41	1.80
PPIAL4A	peptidylprolyl isomerase A (cyclophilin A)-like 4A	196	up		BBMX2	BNA binding motif protein X-linked 2	157
PPIAL4A	peptidylprolyl isomerase A (cyclophilin A)-like 4A	1.90	up		RCOR2	REST corepressor 2	2.27
PPIAL4A	peptidylprolyl isomerase A (cyclophilin A)-like 4A	1,82	up		RFESD	Rieske (Fe-S) domain containing	1,52
PPOY	protoporphyripogon oxidato	107	down		DEV 2	regulatory factor X, 2 (influences HLA class II	2.25
TION	protoporpriyrinogen oxidase	1,07	0000		10 72	expression)	2,20
PPP1R35	protein phosphatase 1, regulatory subunit 35	1,73	up		RFX7	regulatory factor X, 7	1,57
PPP1R3C	protein phosphatase 1, regulatory subunit 3C	1,95	up		RGAG4	retrotransposon gag domain containing 4	1,80
PPP1R3D	protein phosphatase 1, regulatory subunit 3D	1,80	up		RGCC	regulator of cell cycle	1,53
PPP2GA	protein phosphatase 2, catalytic subunit, alpha isozyme	1,00	up		RUDDO	regulator of G-protein signaling 19	2,02
PPP2B2D	protein phosphatase 2, catalytic subunit, beta isozyme	161	up		RHBDI 3	rhombold domain containing 2	2.07
PPP2R5D	protein phosphatase 2, regulatory subulit D, delta	1,53	down		RHOA	ras homolog family member A	1,93
PPP4R4	protein phosphatase 4, regulatory subunit 4	1,62	down		RHOD	ras homolog family member D	1,58
PPP6R2	protein phosphatase 6, regulatory subunit 2	1,54	down		RHOT2	ras homolog family member T2	1,77
PPP6R3	protein phosphatase 6, regulatory subunit 3	1,57	down		RHPN1	rhophilin, Rho GTPase binding protein 1	1,65
DDDC1	peroxisome proliferator-activated receptor gamma,	101			PUDNO	rhonhilin Bho GTPare binding protein 2	151
FFRGI	coactivator-related 1	1,91	uμ		inneni2		1,31
PRAF2	PRA1 domain family, member 2	1,60	down		RLTPR	RGD motif, leucine rich repeats, tropomodulin domain	1,97
						and proline-rich containing	
PRAM 1	PML-RARA regulated adaptor molecule 1	1,60	down		RNF112	ring finger protein 112	1,98
PRCD	progressive rod-cone degeneration	1,72	up		RNF113A	ring tinger protein 113A	2,03
PRDM 11	PR domain containing 11	1,51	up		RINE 114	ring ringer protein 14	1,70
PRICKI F4	nrickle homolog 4 (Drosophile)	165	οφ down		RNF 152	ring finger protein 152	166
PRKAA2	protein kinase, AMP-activated, alpha 2 catalytic subunit	1,52	down		RNF216	ring finger protein 216	1,51
00//1.00	protein kinase, AMP-activated, gamma 2 non-catalytic	105			DNEGO	sing finger protein 20	0.50
PHKAG2	subunit	1,95	up		HNF39	und under broteiu 3a	∠,5∀
PRKD3	protein kinase D3	1,60	up		RNH1	ribonuclease/angiogenin inhibitor 1	2,15
PRKRA	protein kinase, interferon-inducible double stranded RNA	1.54	up		ROR2	receptor tyrosine kinase-like orohan recentor ?	1.74
	dependent activator	.,				and a second sec	
PRLHR	protactin releasing hormone receptor	2,30	down		RPAP1	RNA polymerase II associated protein 1	1,71
PHM I /	protein arginine metnyitransrefase /	1,87	up down		HPIA	ribuse 3-phosphate isomeráse A	1,01
PROP1	PROP paired-like homeobox 1	4,39	down		RPI 12	ribosomal protein L12	2,01
0000	proline rick E (repol)	170			DDI 17	ribosomal protoin 17	2 00

RPI 18	rihosomal protain I 18	2 43	10	SI C25436	solute carrier family 25 (pyrimidine nucleotide carrier	167	10
RPI 21	ribosomal protein I 21	2.46		81.0254.47), member 36 solute corrier family 25 member 47	192	down
RPL21	ribosomal protein L21	2,40	up	SLC25A52	solute carrier family 25, member 52	1,91	down
RPL21	ribosomal protein L21	1.83	up	SLC2A4	solute carrier family 2 (facilitated glucose	1.67	down
RPI 21	ribosomal protein 21	159		ELC2A4RO	transporter), member 4	102	down
RPL21	ribosomai protein L2 I	1,56	up	SLUZA4HG	solute carrier family 2 (facilitated glucose	1,92	down
RPL22	ribosomai protein L22	1,55	up	SLG2A8	transporter), member 8	1,56	up
RPL23	ribosomal protein L23	3,03	up	SLC30A1	solute carrier family 30 (zinc transporter), member 1	1,67	up
RFL29	i bosona proteiri 229	2,07	up	3203048	solute carrier family 31 (copper transporter), member of	1,80	up
HPL38	ribosomai protein L38	4,08	up	SLC31A1	1	1,61	up
RPL7A RPL9	ribosomal protein L7a	2,32	up	SLC35E3 SLC35E4	solute carrier family 35, member E3	1,67	up
RPL9 RPN2	ribophorin II	1.61	up up	SLC35E4	solute carrier family 35, member E4 solute carrier family 35, member F2	1.58	up
RPP14	ribonuclease P/M RP 14kDa subunit	1,56	up	SLC36A3	solute carrier family 36, member 3	1,52	up
RPP25	ribonuclease P/M RP 25kDa subunit	2,11	down	SLC36A4	solute carrier family 36 (proton/amino acid	1,58	up
BPP38	ribonucleases P/MRP 38kDa subunit	108	10	SI C3842	symporter), member 4 solute carrier family 38, member 2	192	
RPS10	ribosomal protein S10	2,88	up	SLC38A5	solute carrier family 38, member 5	1,82	down
RPS13	ribosomal protein S13	4,78	up	SLC38A7	solute carrier family 38, member 7	1,87	down
RPS26 RPS2P45	ribosomal protein S26 ribosomal protein S2 pearlingene 45	2,64	up	SLC39A5	solute carrier family 39 (zinc transporter), member 5 solute carrier family 45 member 4	1,67	down
DDCc	ribosoma protein 62 pacadogene 45	7.74		SLC48A1	colute carrier family 49 (home transporter) member 1	2 12	down
AF30	hoosonia protein ao	7,71	up	3004671	solute carrier rainity 46 (neme transporter), member 1	2,12	down
RPS6KA1	ribosomal protein S6 kinase, 90kDa, polypeptide 1	1,57	up	SLC48A1	solute carrier family 48 (heme transporter), member 1	1,99	up
D D C C K A C	discound and the CO Manage COMPA and the solid sign			0.0444	solute carrier family 4, sodium borate transporter,	0.00	
HPS6KA3	ribosomal protein S6 kinase, 90kDa, polypeptide 3	1,81	up	SLC4A11	member 11	2,99	down
RTDR1	rhabdoid tumor deletion region gene 1	1,53	ир	SLC4A5	solute carrier family 4 (sodium bicarbonate	1,63	up
					solute carrier family 5 (sodium/olucose		
RIELI	regulator of telomere elongation helicase 1	2,02	down	SLC5A1	cotransporter), member 1	1,85	up
RWDD2A	RWD domain containing 2A	1,54	down	SLC5A 10	solute carrier family 5 (sodium/sugar cotransporter),	1,69	up
					solute carrier family 6 (amino acid transporter).		
HXFP4	relaxin/insulin-like family peptide receptor 4	1,76	up	SLC6A14	member 14	1,55	up
RXRA	retinoid X receptor, alpha	1,66	down	SLC6A 19	solute carrier family 6 (neutral amino acid	2,88	down
					solute carrier family 6 (neurotransmitter transporter)		
RYBP	RING1 and YY1 binding protein	1,94	up	SLC6A6	member 6	1,98	up
S1PR3	sphingosine-1-phosphate receptor 3	1.61	down	SLC8A2	solute carrier family 8 (sodium/calcium exchanger),	1.57	down
					member 2 solute carrier organic anion transporter family		
SAMD1	sterile alpha motif domain containing 1	1,61	up	SLCO4C1	member 4C1	1,57	down
SAMD4A	sterile alpha motif domain containing 4A	1,52	down	SLFNL1	schlafen-like 1	1,69	down
SAP30L	SAP30-like	1,98	up	SLIRP	SRA stem-loop interacting RNA binding protein	1,83	up
SASS	spindle assembly 6 homolog (C. elegans)	180	down	SMAD/ SMAP1	small ArtGAP 1	1.71	un
					SWI/SNE seleted metric associated actin dependent	.,	4
SATB1	SATB homeobox 1	1,85	up	SMARCA4	regulator of chromatin, subfamily a, member 4	1,84	up
					·····		
SC5D	sterol-C5-desaturase	1,93	up	SMARCC1	SWI/SNF related, matrix associated, actin dependent	2,15	up
					regulator of chromatin, subfamily c, member 1		
00454	00			0140004	SWI/SNF related, matrix associated, actin dependent	407	
SCAFII	Shi-related CTD-associated factor fi	2,04	up	SMANCOT	regulator of chromatin, subfamily d, member 1	1,67	up
					SWI/SNE related matrix secondated actin dependent		
SCAND2P	SCAN domain containing 2 pseudogene	1,63	down	SM ARCD2	regulator of chromatin, subfamily d, member 2	1,81	up
SCD5	stearoyl-CoA desaturase 5	2,00	down	SMARCE1	SWI/SNF related, matrix associated, actin dependent	2,26	up
					regulator or chromatin, subranny e, member 1		
SCG3	secretogranin III	1,53	down	SM G1	SM G1phosphatidylinositol 3-kinase-related kinase	2,37	up
SCN3A	sodium channel, voltage-gated, type III, alpha subunit	1.50	up	SM OC2	SPARC related modular calcium binding 1	1.88	up
SCN3B	sodium channel, voltage-gated, type III, beta subunit	1,84	down	SM PDL3 B	sphing omyelin phosphodiesterase, acid-like 3B	2,00	up
SCN4B	sodium channel, voltage-gated, type IV, beta subunit	1,69	up	SM URF1	SM AD specific E3 ubiquitin protein ligase 1	1,54	up
SCRT1	socium channel, non-voltage-gated I, gamma subunit scratch family zinc finger 1	4.49	down	SNAP25	snail ramiy zinc ringer 1 synaptosomal-associated protein, 25kDa	1.62	up
SCTR	secret in receptor	2,05	down	SNAP29	synaptosomal-associated protein, 29kDa	1,98	up
SCYL2	SCY 1-like 2 (S. cerevisiae)	2,63	up	SNCG	synuclein, gamma (breast cancer-specific protein 1)	1,68	down
SDC3	syndecan 3 syndecan 4	1,52	down	SND1-IT1 SND1-IT1	SND1intronic transcript 1 (non-protein coding) SND1intronic transcript 1 (non-protein coding)	2,23	down
SDHAF2	succinate dehydrogenase complex assembly factor 2	2,07	up	SNURF	SNRPN upstream reading frame	1,57	down
SDHD	succinate dehydrogenase complex, subunit D, integral	2.02		SNX 13	sorting nexin 13	151	un
0014	membrane protein	0.50		Chill 40		450	
SEC14L1	SEC14-like 1 (S. cerevisiae)	1.82	up	SNX3	sorting nexin 3	1,58	up
SEL1L	sel-1 suppressor of lin-12-like (C. elegans)	1,61	up	SOCS7	suppressor of cytokine signaling 7	1,76	down
0511440	sema domain, immuno globulin domain (Ig), transmembrane			00014			
SEMA40	4C	1,54	up	SUGAT	suppressor of glucose, autopriagy associated 1	1,54	down
SEMARC	sema domain, transmembrane domain (TM), and cytoplasmic	156	down	SORRSI	earbin and SH3 domain containing 1	168	10
OFFIC	domain, (semaphorin) 6C	407		000000	and and a bottom and an and a sector and a s	4.70	up
SEPT5	septin 12 septin 5	1,97	down	SOHBS2 SOWAHD	sorbin and SH3 domain containing 2 sosondowah ankvrin repeat domain family member D	1,70	down
SEPT7	septin 7	2,10	up	SOX 12	SRY (sex determining region Y)-box 12	2,11	down
SEPT7	septin 7	1,87	up	SOX 17	SRY (sex determining region Y)-box 17	1,65	down
SERF2	small EDRK-rich factor 2	4,39	up	SOX21	SRY (sex determining region Y)-box 21	1,87	down
SERPINE 13	servine incorporator 3 servin pentidase inhibitor, clade B (ovalbumin), member 13	153	up	SP5	Sn5 transcription factor	2,53	down
SERPINB2	serpin peptidase inhibitor, clade B (ovalbumin), member 2	2,27	up	SPAG9	sperm associated antigen 9	1,51	up
SERTAD2	SERTA domain containing 2	1,51	up	SPANXB2	SPANX family, member B2	1,58	up
SESN2	sestrin 2	1,65	down	SPATA2	spermatogenesis associated 2	1,51	up
SETD4 SETD8	SET domain containing 4 SET domain containing (lysine methyltransferase) 8	1,75	up	SPATA25 SPATA32	spermatogenesis associated 25 spermatogenesis associated 32	1.68	up
SETD9	SET domain containing 9	1,53	up	SPATC 1L	spermatogenesis and centriole associated 1-like	1,95	down
SF3A1	splicing factor 3a, subunit 1, 120kDa	2,00	up	SPHAR	S-phase response (cyclin related)	1,79	up
SF3B1	splicing factor 3b, subunit 1, 155kDa Still homolog, spindle separably appointed (uppet)	2,36	up	SPN	sialophorin	1,64	up

1. DEGs, differentially expressed genes.

Table S5. Epidermal age-modulated genes in plucked hair shaft shared with previous study using tape strip.

Approved Symbol ¹	HGNC Approved Name ¹	HGNC Approved Symbol ¹	HGNC Approved Name ¹
ABCC6	ATP-binding cassette, sub-family C (CFTR/MRP), member 6	CYHR1	cysteine/histidine-rich 1
ABCE1	ATP-binding cassette, sub-family E(OABP), member 1	CYP4F2	cytochrome P450, family 4, subfamily F, polypeptide 2
ABHD1	abhydrolase domain containing 1	DAB2	Dab, mit ogen-responsive phosphoprotein, homolog 2 (Drosoph
ACBD4	acyl-CoA binding domain containing 4	DBN1	drebrin 1
ACTR1B	ARP1actin-related protein 1 homolog B, centractin beta (yeast)	DBP	D site of albumin promoter (albumin D-box) binding protein
ADD3	adducin 3 (gamma)	GC	group-specific component (vit amin D binding protein)
ADRBK2	adrenergic, beta, receptor kinase 2	HSD17B4	hydroxysteroid (17-beta) dehydrogenase 4
AEG3L 1P	AFG3-like AAA ATPase 1, pseudogene	DENINDIC DESI2	desumovlating isopentidase 2
AGPAT4	1-acylglycerol-3-phosphate O-acyltransferase 4	DFFA	DNA fragmentation factor, 45kDa, alpha polypeptide
ALOX5AP	arachidonate 5-lipoxygenase-activating protein	DHX34	DEAH (Asp-Glu-Ala-His) box polypeptide 34
AMDHD1	amidohydrolase domain containing 1	DMBX1	diencephalon/mesencephalon homeobox 1
ANKEY1	ankyrin repeat and FYVEdomain containing 1	DNAH11	dynein, axonemal, heavy chain 11
AP2A2	adaptor-related protein complex 2, alpha 2 subunit	DNAJB11	DnaJ (Hsp40) homolog, subfamily B, member 11
APH1B	APH1B gamma secret ase subunit	DNM1P35	DNM1pseudogene 35
APLP2	amyloid bet a (A4) precursor-like protein 2	DOCK3	dedicator of cytokinesis3
APPBP2	amyloid bet a precursor protein (cytoplasmic tail) binding protein 2	DRD4	dopamine receptor D4
AQP2	ADB sites detien faster 1	DSC2	desmocollin 2
ABHGEE25	Bho quanine nucleotide exchange factor (GEE) 25	DUX4	double homeobox 4
ARHGEF3	Rho guanine nucleotide exchange factor (GEF) 3	DVL3	dishevelled segment polarity protein 3
ARID5B	ATrich interactive domain 5B (MRF1-like)	EFHD2	EF-hand domain family, member D2
ARL3	ADP-ribosylation factor-like 3	ELOVL6	ELOVL fatty acid elongase 6
ARL6IP1	ADP-ribosylation factor-like 6 interacting protein 1	EMILIN1	elastin microfibril interfacer 1
ARRDC1	arrest in domain containing 1	ENC1	ectodermal-neural cortex 1(with BTB domain)
ATCAY	ataxia, cerebellar, Caymantype	ENPP4	ectonucleotide pyrophosphatase/phosphodiesterase4 (put at
ATG16L1	autophagy related 16-like 1 (S. cerevisiae)	EPAS1	endot helial PAS domain protein 1
ATOH7	at onal homolog 7 (Drosophila)	EPB41L4B	erythrocyte membrane protein band 4.1like 4B
ATP 1A4	ATPase, Na+/K+transporting, alpha 4 polypeptide	EPHA4	EPH receptor A4
ATP6V1A	ATPase, H+transporting, lysosomal 70kDa, V1subunit A	ERCC6L2	excision repair cross-complementing rodent repair deficiency
			complement at ion group 6-like 2
BCAM	basal cell adhesion molecule (Lutheran blood group)	ERG	v-etsavianerythroblastosisvirusE26 oncogene homolog
BCA12 BCAN	branched chain amino-acid transaminase 2, mit ocnondriai	ERINI EXOC3L2	endoplasmic reficulum to nucleus signaling i
		2.222	fatty acid binding protein 3, muscle and heart (mammary-deri
BCKDK	branched chain ket oacid dehydrogenase kinase	FABP3	growth inhibitor)
BCL7A	B-cell CLL/lymphoma 7A	FADS2	fatty acid desaturase 2
BHLHE23	basic helix-loop-helix family, member e23	FAIM3	Fasapoptotic inhibitory molecule 3
BHLHE23	basic helix-loop-helix family, member e23	FAM101B	family with sequence similarity 101, member B
BNIP3L	BCL2/adenovirusE1B 19kDa interacting protein 3-like	FAM129B	family with sequence similarity 129, member B
BRAT1	BBCA1-associated ATM activator 1	FAM21C	family with sequence similarity 25, member C
BTF3	basic transcription factor 3	FAT2	FATatypical cadherin 2
BTN3A3	but yrophilin, subfamily 3, member A3	FBXL17	F-box and leucine-rich repeat protein 17
BTG1	B-cell translocation gene 1, anti-proliferative	FBXL7	F-box and leucine-rich repeat protein 7
C2	complement component 2	FBX09	F-box protein 9
C5AH1	complement component 5a receptor 1	FGN1	ficolin (collagen/fibrinogen domain containing) 1
CACNA1B	calcium channel, voltage-dependent, Ntype, alpha 18 subunit	FGD6	FYVE BhoGEE and PH domain containing 6
CACNG7	calcium channel, volt age-dependent, gamma subunit 7	FGF5	fibroblast growth factor 5
CASD1	CAS1domain containing 1	FKBP1A	FK506 binding protein 1A, 12kDa
CASP5	caspase 5, apoptosis-related cysteine peptidase	FOXG1	forkhead box G1
CAV1	caveolin 1, caveolae protein, 22kDa	FOXJ1	forkhead box J1
CBS	cystathionine-beta-synthase	FOXN3	forkhead box N3
CCDC144NI	colled-coll domain containing 134	FOXP1 FOXO1	forkheadbox P1
CCDC90B	coiled-coil domain containing 90B	FBMD4A	FEBM domain containing 4A
CCND2	cyclin D2	FUBP3	far upstream element (FUSE) binding protein 3
CCND3	cyclin D3	FXN	frataxin
CD109	CD109 molecule	FZR1	fizzy/cell division cycle 20 related 1 (Drosophila)
CD1E	CD1e molecule	GALNT6	UDP-N-acetyl-alpha-D-galactosamine:polypeptideN-
00244	CD044 malagula, patural killar gall recent or 2R4	ODNE	acetylgalactosaminyltransterase6(GalNAc-16)
CDC42EP1	CDC42 effector protein (Bho GTPase binding) 1	GEOD1	glucose-fructose oxidoreductase domain containing 1
	carcinoembryonic antigen-related cell adhesion molecule 1 (biliary		a
CEACAM1	glycoprotein)	GG11	gamma-glutamyltransferase 1
CEACAM4	carcinoembryonic antigen-related cell adhesion molecule 4	GGT3P	gamma-glut amylt ransferase 3 pseudogene
CEBPA	CCAAT/enhancer binding protein (C/EBP), alpha	GGTLC2	gamma-glut amylt ransferase light chain 2
CHAC2	GnaG, cation transport regulator homolog 2 (E coli)	GIT2	Gprotein-coupled receptor kinase interacting Arf GAP 2
CIDECP	cell death-inducing DFFA-like effector c pseudogene	GLDC	gap junction protein, gamma 2, 4/KDa alveine debydrogenase (decarboxylating)
CIRBP	cold inducible RNA binding protein	GLIS3	GLIS family zinc finger 3
CLCF1	cardiotrophin-like cytokine factor 1	GLRX	glutaredoxin (thioltransferase)
CLINT1	clathrin interactor 1	GM2A	GM2 ganglioside activator
CLPTM1L	CLPTM1-like	GNG13	guanine nucleotide binding protein (Gprotein), gamma 13
CMIP	c-Maf inducing protein	GPR115	Gprotein-coupled receptor 115
CNOT4	CCR4 NOT transcription complex, subunit 4	GPR62	Gprotein-coupled receptor 62
COL 19.4.1	collagen type XVIII alpha 1	GRIN2D	giulamate receptor, ionotropic, N-methyl D-aspartate 2D
CORT	cortistatin	GYPC	global and an and a priorination into, polypeptide 4, sok Da
CRABP1	cellular retinoic acid binding protein 1	HAPLN4	hyaluronan and proteoglycan link protein 4
CRHR1	corticot ropin releasing hormone recept or 1	HCP5	HLA complex P5 (non-protein coding)
CRTC1	CREB regulated transcription coactivator 1	CYCSP5	cytochrome c, somatic pseudogene 5
CRTC2	CREB regulated transcription coactivator 2	HGD	homogent isat e 1,2- dioxygenase
CSAD	cysteine sulfinic acid decarboxylase	HGS	hepatocyte growth factor-regulated tyrosine kinase substrate

Keywords: keratinocytes, aging, reconstructed skin, keratinocyte stem cells, transit amplifying cells

Running title: Age versus neonatal keratinocytes

Abstract

One of the major unanswered questions regarding the morphological characteristics of the skin during the aging process is whether the thickness of its main layers is altered. Some studies propose that stem cells are responsible for maintaining the proliferative potential of the epidermis in vivo, while others argue that this potential is lost during the aging process. In this study, we compare keratinocytes from neonatal and 26-, 36- and 48-year-old groups to evaluate their proliferative and differentiation potential, both in monolayer cultures and in skin reconstituted in vitro. Cells isolated from neonatal donors show higher expression levels of Ki67 and keratins 10 and 14. Furthermore, the number of neonatal cells in the G2/M phase of the cell cycle was strikingly higher. To determine the number of stem cells present in this population, we used the $\beta 1$ and $\alpha 6$ integrins as molecular markers. Interestingly, we did not observe any differences among these cells in culture. In the reconstituted skin model, the cells isolated at different ages were able to undergo epidermal proliferation and differentiation in a similar manner. The expression of Ki67 and of keratins 10 and 14 were also higher in skin reconstituted with cells isolated from neonatal donors. In conclusion, cultured neonatal cells have a higher proliferative capacity and differentiation potential relative to adult cells isolated at different donor ages, as revealed by the markers tested. The monolayer and reconstituted skin models generated from cultured cells represent important alternative methods to investigate the process of skin aging.

Introduction

All cells and organs of the body age gradually, and the skin can be used as a marker of this inevitable process. Skin is the largest organ of the human body and is a self-renewable tissue that is responsible for numerous physiological functions such as thermoregulation, protection against pathogens and ultraviolet radiation, tactile sensations, secretions, and excretion of toxins (Geusau *et al.*, 2001; Yamaguchi *et al.*, 2006; Kirschner *et al.*, 2013; Polak *et al.*, 2013). Moreover, it is the first organ that shows the health and well-being of the individual and reflects numerous aesthetic parameters.

The skin consists of two compartments: the epidermis and the dermis (Gangatirkar *et al.*, 2007). The epidermis is a stratified tissue that is histologically composed of four layers: the basal layer, containing epidermal stem cells (SC) and a population of transient amplifying cells (TA); the spinous layer, containing differentiating cells; the granular layer, containing cells that have already differentiated; and the stratum corneum, which is populated by dead cells (Rizvi and Wong, 2005; Gangatirkar *et al.*, 2007).

Aged skin is thinner and has a lower healing potential compared with youthful skin. Nevertheless, it is still able to heal and regenerate its epithelium, showing that it retains, at least partially, cell renewal potential (Webb and Kaur, 2006; Racila and Bickenbach, 2009; Winter and Bickenbach; 2009). Numerous studies in the literature have addressed whether the characteristics of skin cells are related to the anatomical morphology of the skin. One of the major points discussed in these studies is the thickness of the epidermal layer. Many studies describe a flattening at the epidermal-dermal junction and a decrease in the thickness of these layers in aged skin (Fenske and Lober 1986; Fenske and Conard, 1988). However, some authors still argue against these points, showing that there is no consensus on this topic. Different studies have reported large variations in the epidermal and dermal thickness during the aging process. However, it is important to note that these studies have compared different parameters, such as the anatomical sites and phenotypic features of the

125

individuals examined (Ya-Xian *et al.*, 1999; Nozdrin *et al.*, 2011; Baroni *et al.*, 2012; Crisan *et al.*, 2012; Waaijer *et al.*, 2012; Tsugita *et al.*, 2013; Shlivko *et al.*, 2013).

One explanation for the decreased epidermal thickness is related to the decreased proliferative potential of its main cell type, the keratinocyte, during the aging process. Grove and Kligman (1983) evaluated cell renewal in the human epidermis using a fluorescent marker. These authors reported that the dye disappeared from the stratum corneum at 20 days in young adults, while it persisted for up to 30 days in older adults. However, these authors note that the number of layers of horny cells did not change with increasing age. This finding was proposed to result from a decreased proliferation of epidermal cells. This study also reported that cells maintain a constant renewal rate in the early years of life that decreases over time, with a dramatic reduction after 50 years (Grove and Kligman, 1983). Subsequent studies have attempted to explain possible differences in the thickness of the epithelium *in vivo* by correlating the presence of SC with the proliferative capacity of keratinocytes *in vitro*. Stem cells derived from adult tissues in some regions of the body are defined as rare and relatively quiescent, with the capacity to constantly self-renew and regenerate tissues during homeostasis. Some authors claim that epidermal SC appears to resist aging. They do not show age-related changes in gene expression, cell number and telomere length, thus maintaining the capacity to respond to environmental changes. In addition, these cells do not show defects associated with increasing levels of reactive oxygen species encountered during the process of cellular aging (Li et al., 2004; Racila and Bickenbach, 2009). However, other studies suggest that the transient amplifying cells also possess multipotency and an extensive capacity for tissue regeneration (Clayton et al., 2007; Schlüter et al., 2011). Another important issue to note is that some authors claim that it is more difficult to isolate and to maintain cultured keratinocytes from elderly donors compared with young or neonatal donors. Youn et al. (2004) reported that this can be explained by cellular senescence, chronological aging, or repeated sub-culture that induces the loss of SC in keratinocyte cultures and *in vitro* reconstituted epidermis models.
By comparing the literature, we have observed that the many different findings may correlate, and depend upon, the experimental model used in each study. Our study focuses on *in vitro* models, which are extensively used due to their ease of production, practicality and reproducibility. Therefore, we compare keratinocytes from neonatal and 26-, 36- and 48-year-old groups in this study to determine the differences in their proliferative capacity and differentiation potential, both in a monolayer model as well as in an *in vitro* reconstituted skin model. We also determined the number of stem cells (SC) and transient amplifying cells (TA) present in each of these populations. The data presented here confirm that the proliferation capacity and differentiation potential of neonatal and adult cells is significantly different for all conditions examined, while the cells isolated from adult donors do not show striking differences *in vitro*.

Materials and methods

Cell culture

The primary cells used in this work were obtained from Cascade Biologics (Portland, OR, USA). The keratinocytes used were isolated at different donor ages: neonatal and 26, 34, 36 and 48 years old (lots 979196, 950451, 952853, 1030541, 1249380 and 1139070, respectively). Fibroblasts were isolated from a 37-year-old donor (lot 759506). Fibroblasts were grown in Dulbecco's modified Eagle's medium (DMEM) (Gibco, Grand Island, NY, USA) supplemented with 10% fetal bovine serum (FBS, Gibco), 50 U/mL penicillin and 50 μ g/mL streptomycin (Gibco). Keratinocytes were maintained in Epilife media (SKU # M-EPICF-500, Cascade Biologics) supplemented with Human Keratinocyte Growth Supplement (HKGS, SKU # S-001, Cascade Biologics). All cells were maintained at 37°C under 5% CO₂.

Fluorescence microscopy

Keratinocyte monolayer cultures derived from donors of different ages were plated in 96-well plates. After the incubation period, the cells were fixed with methanol (Sigma, St. Louis, MO, USA) for ten minutes followed by three washes with PBS (Sigma, diluted 10x). The primary antibody staining was performed overnight at 4°C. The antibodies used were Ki-67 (clone B56, BD Pharmingen, Biosciences, Bedford, MA, USA), keratin 10 MAb Ms (Abcam, ab9026; Cambridge, Cambridgeshire, England) and keratin 14 MAb Ms (Abcam, ab7800). The antibodies were diluted in PBS containing 2% BSA (Sigma, 9576). Following the primary antibody incubation, the cells were washed with PBS and incubated with the secondary antibodies, Alexa Fluor 488 goat anti-mouse (Molecular Probes, Eugene, OR, USA; A11029) or Alexa Fluor 488 goat anti-rabbit (Molecular Probes, A11034), diluted in PBS containing 1% BSA and 0.1% Tween 20 for one hour (Amersham Biosciences, Uppsala, Uppsala Country, Sweden, 17-1316-01). The cells were washed with the same buffer, and then fixed with NucBlue cell stain (Molecular Probes, R37606) for nuclear staining. All images were acquired using an Image Xpress Micro microscope (Molecular Devices). The fluorescence intensity analyses were performed with the MetaXpress 4.0 software.

Cell cycle analysis

DAPI, which binds stoichiometrically to DNA, was used to quantitatively assess DNA content. Seventy thousand cells were centrifuged at 1000 rpm for 5 min at 4°C. The pelleted cells were fixed in ice-cold 70% ethanol for 30 minutes and washed twice in PBS. Cells were subsequently incubated for 1 h at room temperature with DAPI, and then evaluated by a FACS Aria I flow cytometer using the DIVA software (Becton Dickinson, San Diego, CA, USA). Ten thousand events were analyzed per experiment. The processed single cells were plotted on gated histograms to calculate the number of cells in the G1, S and G2/M phases.

Determination of stem cells in the cultures isolated from donors of different ages

To determine the percentage of KSC in the samples isolated from donors of different ages, 10^5 cells from each individual donor were used. Following trypsinization and washing with PBS, the cells were blocked with 500 µL of BSA Stain Buffer (BD, 554657) and double-stained with the following antibodies: CD29 (BD, 555443) and CD49f (BD, 551129). After 30 minutes of labeling at 4°C in the dark, the cells were centrifuged at 6300 rpm for 3 minutes, resuspended in PBS and kept at 4°C until analysis on a FACS Aria I flow cytometer (Becton Dickinson). Ten thousand events were acquired per experiment. The data were analyzed using the DIVA software.

In vitro skin reconstitution

The skin reconstitution model was adapted from Gangatirkar *et al.* (2007). Briefly, the dermal equivalent was prepared using 6×10^4 fibroblasts embedded in a type I collagen matrix (BD). After polymerization of the dermal equivalent, 1.2×10^5 keratinocytes isolated from donors of different ages (neonatal and 26, 34, 36 and 48 years old) purchased from Cascade Biologics or freshly isolated were plated above the dermal layer. After 24 hours, the equivalent was kept on an air-liquid interface while maintaining contact with the differentiation medium consisting of 15% of DME (Gibco, 12800-017), 5% Ham's F12 (Gibco, 114971), 2% Fetal Bovine Serum (Gibco, F0926), 0.5 µg/mL Transferrin (T-8158, Sigma), 5 µg/mL Insulin (I-9278, Sigma) and 10 ng/mL EGF (human epidermal growth factor, 53003-18, Gibco). After 10 days on the air-liquid interface, the reconstituted skin was fixed in 4% formaldehyde (Sigma, F8775).

Immunostaining

After deparaffinization and rehydration, antigen retrieval was performed in Tris- EDTA, pH 9.0 (S3307, Dako, Carpinteria, CA, USA), using a water bath

heated with steam and maintained at 97°C for 30 minutes. The slides were cooled to room temperature for 20 minutes and then washed with distilled water and TBST buffer (Tris-buffered saline with 0.01% Tween-20, 3306, Dako). The slides were blocked with 2% BSA for 2 hours at 37°C. Immunohistochemical analyses were performed with the following primary antibodies: Ki-67 (clone B56, BD Pharmingen, 556027), keratin 10 MAb Ms (Abcam, ab9026) and keratin 14 mAb Ms (Abcam, ab7800) ARK (Animal Research Kit, K3954, Dako). The primary antibody was omitted in the negative controls.

Statistical analyses

Cell cycle and fluorescence microscopy analyses are expressed as means ± SEM. The Graph Pad Prism 6 (version 6.00 for Windows Vista, Graph Pad Software, San Diego, CA, USA) software and a two way ANOVA test were used to perform statistical analyses. A one-way ANOVA with multiple comparison test (Tukey–Kramer Multiple Comparisons Test) was used for data analyses. We used correlation analysis to identify potentially causal associations between variables.

Results

Cell differentiation and proliferation in monolayer cultures

To assess the differences among keratinocytes isolated from donors of different ages, monolayer cultures of cells isolated from neonatal and from 26-, 36- and 46-year-old donors were stained with a nuclear marker of cell proliferation, Ki67, and markers of cell differentiation, keratin 10 and 14. As shown in Figure 1, the neonatal cells display both an increased number of Ki67-labeled nuclei and a more pronounced staining with this cell proliferation marker, indicating higher expression levels of Ki67 in the neonatal cells. A quantification of the fluorescence intensity of Ki67 staining revealed a significant difference between the neonatal and adult cells (p<0.05). Higher expression levels were also observed for the

differentiation markers keratin 10 (p<0.01) and keratin 14 (p<0.05) in neonatal keratinocytes compared with adult keratinocytes. However, no differences were observed among the keratinocytes isolated from the adults of different ages.

Cell cycle analyses

Because Ki67 expression analyses in monolayers revealed an increased expression of this proliferation marker in neonatal cells (Figure 1), we performed cell cycle analyses to determine whether there is indeed a difference in cell cycle phases among cells isolated from donors of different ages. The cell cycle analyses were performed by flow cytometry, using DAPI staining of the DNA content to differentiate between the cell cycle phases. Figure 2a shows the histograms obtained from these analyses. This figure shows the distribution of the number of cells in each cell cycle phase for the four ages analyzed. Figure 2b shows that the neonatal cultures exhibit a significant decrease in the number of cells in the G0/G1 phase (p <0.01) and a striking increase in the number of cells in the G2/M phase (p <0.001) compared with adult cells. The only difference detected among the adult cells was a reduction in the number of S phase cells from the 48-year-old donor (p <0.05); no significant differences were observed in the other phases analyzed.

Analysis of keratinocyte stem cells

To determine whether the differences in cell proliferation were related to changes in the number of KSC (keratinocyte stem cell) present in the neonatal and adult cell populations, we tested two typical markers of KSC: the β 1 and α 6 integrin. The KSC population should be double positive for the β 1 (CD29) and α 6 integrin (CD49f) markers. The KSCs are distinguished from the transient amplifying cells (TAs) by exhibiting a strong, bright signal for β 1 integrin, whereas TA cells exhibit a dim signal. The α 6 integrin signal is bright for both populations. Both cell types can be accordingly identified as KSC^{β 1bri,\alpha6 bri} differentiating cells and TA^{β 1dim,\alpha6 bri} differentiated keratinocytes (Kaur and Li, 2000).

Figure 1. Fluorescence microscopy analysis of proliferation (Ki67) or differentiation (keratin 10 and 14) markers and their respective negative controls. Cells isolated from neonatal or 26-, 36- and 48-year-old adult donors were used in these analyses. The graphs on the right hand side show the ratio of fluorescence intensity per total cell number for the three marker proteins tested. A significantly higher number of neonatal cells (p <0.05) demonstrate positive staining for the three markers tested compared with adult cells. Magnification 20x

Figure 2. Cell cycle analyses of keratinocytes isolated from donors of different ages. (A) The histograms show the cell cycle distribution according to the DNA content for each age tested. G0/G1, S and G2/M indicate the cell cycle phases. (B) The graphs show the percentage of cells in each cell cycle phase for the four ages tested. Note that the neonatal cells have a smaller number of cells in the G0/G1 (p < 0.01) and a strikingly large number of cells in the G2/M proliferative phase (p < 0.001). On the other hand, the 48-year-old cells show a significant reduction in the number of S phase cells (p < 0.05).

As shown in Figure 3, it was not possible to detect KSCs in any of the cells analyzed because the populations were very homogenous and stained brightly for both the β 1 and α 6 integrins. No differences were observed among the adult cells isolated from donors of different ages (data not shown).

Figure 3. The dotplot and histograms show the $\beta 1$ and $\alpha 6$ integrin staining in neonatal and 48 yearold donor cells. All cells are positive for both markers. Only one population detected shows that cells in culture form a homogenous population, as determined by the expression of the $\beta 1$ and $\alpha 6$ integrin markers.

134

Skin reconstitution using cells from donors of different ages

To examine keratinocyte proliferation and differentiation in a model that mimics human skin, cells isolated from donors of different ages were used to reconstitute skin *in vitro*. As shown in Figure 4, all cells were able to differentiate and form a multi-layered epithelium containing the four main layers of the epidermis (basal, spinous, granular and stratum corneous; HandE staining). As in the monolayer model, more intense Ki67 labeling and an increased number of Ki67-labeled nuclei (indicated by arrows) were observed in the skin reconstituted with neonatal cells relative to skin reconstituted with aged cells. Higher expression levels of keratin 14, a marker for basal cells, were also present in the skin reconstituted with neonatal derived cells. A similar increase in the expression levels of keratin 10, a marker of differentiated cells was observed in the skin reconstituted with neonatal cells; however, it was less pronounced than the increased expression of Ki67 and keratin 14.

Figure 4. Analysis of skin reconstituted *in vitro*. Keratinocytes isolated from different age groups were used to show the proliferation and differentiation potential in a three-dimensional model. The H&E staining shows that all cells have a similar potential to form the main layers of the epidermis. However, neonatal cells show a stronger signal than adult cells for Ki67, keratin 10 and keratin 14 staining. The negative controls for immunostaining are shown. Magnification 20x.

Discussion

One of the most controversial issues in the literature describing the morphological characteristics of skin aging is the proliferation and differentiation of keratinocytes. Some authors claim that there is a decrease in the proliferative potential of these cells during aging, while others argue that there are no detectable differences in the thickness of the epidermis at different ages. Ya-Xian et al. (1999) determined the number of cell layers in the stratum corneum of normal skin at different anatomical locations in the body of 301 volunteers of various ages. These authors reported large variations in the number of cell layers that depended on two factors: body location and genetic variability. In contrast, Baroni et al. (2012) reported no significant age associated differences in the thickness of the epidermal and dermal layers in a study including 218 Caucasian women. However, in a study of 286 Dutch individuals from middle-aged offspring with siblings older than 90 years, and therefore, a genetic predisposition to longevity, and their partners without this favorable genetic condition, Waaijer et al. (2012) demonstrated that epidermal thickness is reduced during the aging process. Furthermore, there were no differences between the genetically privileged and non-privileged individuals. We presumed that the variations among the experimental models used in these studies might explain the different conclusions reached by the investigators. Thus, we compared keratinocytes cultures derived from donors of different ages in this study to evaluate the effects of culture conditions on keratinocyte proliferation and differentiation.

To understand how the experimental conditions affect the proliferative capacity and differentiation potential of keratinocytes, we tested different markers identifying these processes in monolayer and reconstituted skin cultures using cells isolated from donors of different ages (Figure 1). Ki67 is a nuclear antigen present in proliferating cells, but absent from cells in the S phase of the cell cycle (Gerdes *et al.*, 1983; Rahmanzadeh *et al.*, 2010). A previous study of scalps isolated during the autopsies of males between 7 months and 75 years of age (Nozdrin *et al.*, 2011), analyzed the expression of p53, Ki67 and involucrin and determined their

relationship to the proliferative layers of the epidermis. This report found that the epidermis was thinner in children with low p53 and Ki67 expression. This study also reported that the maximum proliferative activity was obtaining in skin isolated from 19- to 21-year-old individuals. Aging was associated with a reduction in the proliferation rate and, consequently, a thinning of the epidermis and an increase in the number of p53-positive cells. No changes were detected in the expression of involucrin. Contrary to the results described by Nozdrin *et al.* (2011), the neonatal cells cultured *in vitro* in this study exhibited higher expression levels of Ki67 compared with adult cells isolated from donors of different ages, both in the monolayer model (Figure 1) and in the *in vitro* reconstructed skin model (Figure 4).

Keratins are major structural proteins synthesized by keratinocytes (Prokshk *et al.*, 2008). Keratinization is the terminal differentiation process of epidermal keratinocytes from the basal layer to the stratum corneum, forming a threedimensional network and a highly dynamic cytoskeleton that is essential for the mechanical stability of epithelial tissues (Arin, 2009; Ramot *et al.*, 2009). During this process, pairs of keratins are expressed in a highly specific manner for each dynamic stage of epithelial differentiation (Moll *et al.*, 2008; Arin, 2009). The keratin family consists of 54 functional genes that have different modes of expression in different skin layers and in different organs, representing physiological and pathological states of epithelial cells and epidermal cells (Ramot *et al.*, 2009). In the epidermis, the transition of keratinocytes from the proliferative basal layer to the spinous layer during the terminal differentiation process is characterized by changes in keratin expression. This involves a change in expression from the basal keratins (keratins 5, 14 and 15) to the suprabasal keratins (type II keratin 1 and subsequently type I keratin 10) (Moll *et al.*, 2008; Arin *et al.*, 2009).

The data presented here show that all cultured keratinocytes, regardless of age, are capable of passing through terminal differentiation as demonstrated by the stratification observed in the *in vitro* reconstituted skin model (Figure 4, HandE). However, neonatal keratinocytes exhibit higher expression levels of keratin 10 and 14, both in monolayer cultures (Figure 1) and in reconstituted skin (Figure 4), although keratin 10 does not seem to be expressed at the same levels as keratin

14. Together, these results reveal that a larger number of neonatal cells have proliferative potential compared with adult cells.

Numerous analyses of epithelial cell kinetics *in vivo* suggest that the sustained cell renewal of the epidermis can be attributed to long-lived SC because the life expectancy of the majority of proliferating epidermal cells (transient amplifying cells) is short, and a rapid loss of those cells occurs due to terminal differentiation within a period of weeks (Morris *et al.*, 1985; Bickenbach *et al.*, 1986, Li *et al.*, 2004). The growth capacity exhibited by the cultured epidermal cells is attributed to the activity of stem cells; once transplanted, cells maintain the ability to renew the epithelium over a longer period of time (Pellegrini *et al.* 1999; Li *et al.*, 2004).

Epidermal stem cells or keratinocyte stem cells (KSCs) are unique among somatic stem cells because, regardless of the age of the skin, the epidermis must be replaced continuously, requiring these cells to function correctly (Webb and Kaur, 2006; Racila and Bickenbach 2009). As their name indicates, KSCs are prekeratinocyte. The cell division of KSCs gives rise to a new population of keratinocytes in culture (Papini *et al.*, 2003). Moreover, after isolation and selection, KSC cultures produce keratinocytes that will differentiate and give rise to the three populations of transiently amplified and differentiated keratinocytes.

Several enrichment protocols have been reported in the literature for the separation of the basal layer of KSC or progenitors (TA), including the use of β 1 integrin (Jones *et al.*, 1995; Kaur and Li, 2000), integrin α 6 and transferrin receptor CD71 (Li *et al.*, 1998; Tani *et al.*, 2000). Thus, we examined the KSC and TA populations present in keratinocyte cultures from donors of different ages (Figure 3). Interestingly, no differences were detected among the cells isolated from donors of different ages, as it was not possible to differentiate the KSC^{β 1bri,\alpha6 bri} from the TA^{β 1dim,\alpha6 bri} populations in cultured keratinocytes. One explanation for this result is that these are cultured, and not freshly isolated cells. Kaur *et al.* (2004) note the importance of working with freshly isolated cells rather than cultured cells to identify and isolate epidermal stem cells. They claim that the expression of the main markers present *in vivo* may be altered following *in vitro* culturing. In our lab,

we have observed that it is possible to separate the KSC population and to obtain thicker epithelia in skin reconstructed *in vitro* (data not shown) by using freshly isolated samples. In addition, the higher expression levels of the keratin 10 differentiation marker observed in the cultured cells could explain the lack of a KSC population (Webb *et al.*, 2004). Another possibility is that the isolation of adult keratinocytes and, therefore, separation of KSC, is more complex compared with neonatal keratinocytes. A study by Gragnani *et al.* (2008) examined primary keratinocytes isolated from the skin of 22 patients with ages ranging between 0 and 15 years and found that the highest number of single cells was obtained in the 0- to 3-year-old group, with approximately 4×10^6 cells. The number of single cells isolated falls to 10^6 in the oldest ages, and a direct inverse relationship was observed between age and the number of isolated cells: as age increased, the number of isolated cells decreased.

In conclusion, this work shows that *in vitro* models are promising tools for studying the epidermal aging process, although some issues, such as the reprogramming of gene expression and the selection of cell subpopulations, still need to be considered. Cultured neonatal cells have a higher proliferative capacity and differentiating potential compared with adult cells. The adult cells derived from donors of different ages did not exhibit differences in their proliferation capacity or differentiation potential in either the monolayer or reconstructed skin models, as determined by Ki67 or keratin 10 and 14 labeling, respectively. KSCs should be studied in freshly isolated cell preparations because reliable markers for KSC identification are still lacking, and the integrins used to enrich stem cell populations are upregulated when keratinocytes are cultured. Finally, this work shows that cultured cells can be used as an alternative method to understanding the differences in the proliferation and differentiation processes between neonatal and adult cells. Future studies are needed to verify whether there are the differences in adult cells freshly isolated from donors of different ages cultured *in vitro*.

4. DISCUSSÃO GERAL

Com base na análise global da expressão de genes, o presente trabalho indica evidências para a regulação molecular associada ao processo de envelhecimento epidermal, mais especificamente de regiões continuamente expostas à radiação solar. O estudo experimental inicial, baseado na avaliação da epiderme obtida com fitas adesivas, evidenciou a regulação de processos biológicos de diferenciação e atividade dos queratinócitos. Processos como proliferação celular não foram enriquecidos, possivelmente porque as células da camada basal da epiderme não puderam ser coletadas devido a limitações da técnica empregada. Considerando amostras coletadas do dorso das mãos, este trabalho representou o primeiro estudo com foco na avaliação do transcriptoma epidermal humano de região exposta ao sol.

É importante notar que alguns estudos já avaliaram os efeitos do envelhecimento em pele humana completa, contendo epiderme e derme. Entretanto, a maioria tem provado dificuldades de interpretação frente à heterogeneidade das amostras biológicas, tanto em termos de varialibidade interindividual como também com relação à complexidade tecidual (Gromov *et al.*, 2003). Visando superar tal dificuldade, as análises de expressão gênica global em nosso trabalho foram conduzidas apenas com material de origem epidermal e com um tamanho amostral significativo, possibilitando um delineamento experimental reforçado e favorecendo o enriquecimento de listas de genes diferencialmente expressos. Além disso, buscando completar as informações já existentes na literatura científica, utilizamos um painel experimental de amplo espectro com relação às faixas etárias avaliadas, segmentado a cada década entre 20 e 80 anos.

Inicialmente, buscando estabelecer comparativos com a grande maioria dos estudos, realizamos uma análise prévia com os indivíduos organizados em dois grupos polarizados quanto ao envelhecimento: abaixo de 50 anos ou jovens e acima de 50 anos ou idosos. Dentre os processos biológicos que apresentaram regulação significativa com o avanço da idade, alguns complementam achados

prévios da literatura, como a indução de apoptose na epiderme fotoenvelhecida, marcada pela presença de queratinócitos apoptóticos (Leyden, 2001; Van Laethem et al., 2005). Um estudo recente avaliou mudanças relacionadas à idade na composição do envelope córneo na pele humana (Rinnerthaler et al., 2013). Corroborando com nossos achados, os autores observaram alterações significativas na expressão dos genes envolvidos nas etapas iniciais de montagem do estrato córneo. Por outro lado, nossos dados mostraram padrões distintos na expressão de genes como loricrina, sugerindo características específicas da regulação gênica epidermal em tecido exposto ao sol. Tal ocorrência poderia ajudar a explicar mudanças clínicas só observadas na pele fotoexposta, como o espessamento epidermal (Leyden, 2001; El-Domyati et al., 2002), que não acomete regiões fotoprotegidas (Lock-Andersen et al., 1997; Makrantonaki e Zouboulis, 2007). Ainda, também evidenciamos modulações em vias metabólicas relacionadas à sinalização de cálcio e sinalização do citoesqueleto de actina, podendo contribuir na elucidação de mecanismos moleculares envolvidos na perda do gradiente epidermal de cálcio (Denda et al., 2003) ou em alterações morfológicas que acometem queratinócitos envelhecidos, que apresentam forma irregular, alargada e achatada (Soroka et al., 2008). Dessa maneira, nossos resultados sugerem um mecanismo diferenciado do envelhecimento epidermal em regiões de pele fotoexposta, incluindo distúrbios na formação do estrato córneo, ainda sem descrição na literatura e com potencial desdobramento em estudos futuros.

Além dos resultados já destacados, utilizamos uma abordagem diferenciada para análise do envelhecimento em nosso modelo experimental. Com base na proposição de que o envelhecimento é um processo contínuo e cumulativo, também realizamos análises com voluntários agrupados em diferentes décadas de vida. Em cada década, utilizamos como critério de inclusão dos voluntários uma variação reduzida ao redor da idade média desejada, como nos grupos de 20 ± 1 ano ou 30 ± 1 ano, por exemplo, visando restringir possíveis componentes de variabilidade individual intragrupo. Por outro lado, a diferença entre as idades médias de cada grupo, de 10 anos, foi mantida constante. Tais definições foaram adotadas no estudo visando facilitar a identificação de características comuns dentro de uma faixa etária específica e que pudessem apresentar variação entre as diferentes idades. Calculando a diferença entre o número de genes com aumento de expressão e aqueles com diminuição de expressão em cada década, observamos um perfil oscilatório ao longo das idades, remetendo à idéia de um equilíbrio dinâmico de regulação constante como o que ocorre em respostas compensatórias de restabelecimento homeostático. Ainda, uma análise adicional foi realizada para identificar genes que tendem a mudar sua expressão de forma contínua ao longo da vida.

No segundo trabalho experimental da tese, uma nova análise de expressão gênica global aplicando microarranjos de DNA foi utilizada para avaliar modulações transcricionais associadas ao envelhecimento da epiderme, desta vez coletada a partir de bulbos de folículos pilosos da região das sobrancelhas. A análise do envelhecimento foi determinada comparando mulheres adultas distribuídas em dois grupos de idade, com menos de 50 anos ou jovens e mais de 50 anos ou idosas, divididas de acordo com o critério biológico da ocorrência de menopausa ao redor dos 50 anos da mulher. Interessantemente, o agrupamento hierárquico espontâneo das amostras biológicas evidenciou uma repartição em dois grupos muito similares ao que se esperava obter com a proposição dos grupos pré e pós-menopausa, reforçando a significância da ocorrência da menopausa na mulher como agente desencadeante de uma mudança sistêmica com grande impacto sobre a pele (Raine-Fenning *et al.*, 2003).

Uma diferença importante que deve ser destacada ao compararmos nossos resultados obtidos a partir da epiderme derivada de fitas adesivas ou folículos pilosos: as camadas ou mesmo os tipos celulares coletados a partir de cada uma das técnicas são significativamente distintos. Enquanto o material proveniente de fitas adesivas deve ser enriquecido em queratinócitos em estágio final de diferenciação das camadas espinhosa ou granulosa (principalmente), o material dos folículos pilosos deve ser rico em células epidermais não diferenciadas ou em estágio inicial de diferenciação, representando nichos biológicos com particularidades funcionais e moleculares (Blanpain and Fuchs, 2009). Além disso,

o processo de diferenciação destas células presentes no folículo piloso é distinto da diferenciação epidermal prevista para regiões interfoliculares, provavelmente envolvendo a ocorrência de eventos moleculares independentes que culminam com a expressão de diferentes tipos de queratina, dentre outros (Schweizer *et al.*, 2007; Jiang *et al.*, 2010; Mascré *et al.*, 2012).

Diferentemente dos resultados obtidos com fitas adesivas, as análises do material epidermal proveniente de pelos de sobrancelhas revelou resultados difíceis de correlacionar com aspectos clínicos e morfológicos do envelhecimento epidérmico. De fato, observou-se uma prevalência de processos biológicos de largo espectro ou generalistas, tais como metabolismo celular, processos biossintéticos e regulação da expressão gênica ou transcrição. Além disso, a modulação de diversas vias de sinalização foi uma característica marcante do envelhecimento deste tipo de material biológico, incluindo genes representativos como proteínas do tipo zinc finger e elementos associados. De acordo com um recente trabalho de Tevy et al. (2013), por razões ainda desconhecidas, há um declínio no ritmo circadiano com a idade. A temporização da divisão e diferenciação de células proliferativas na epiderme do folículo piloso, por sua vez, depende de um controle associado ao ritmo circadiano, de forma que camundongos com ritmo circadiano perturbado apresentam envelhecimento epidermal prematuro e predisposição à tumorigênese (Janich et al., 2011). Assim, estudos futuros poderiam ser conduzidos para estabelecer uma ligação entre a ocorrência de um ritmo circadiano perturbado com a regulação do comportamento de células proliferativas na epiderme do folículo piloso com a idade. Considerando nossos resultados, a desregulação da sinalização celular na epiderme folicular com o envelhecimento pode ser um dos caminhos decisivos para o melhor entendimento destes aspectos.

No terceiro trabalho experimental, buscamos estabelecer um comparativo entre características do envelhecimento epidermal *in vivo* e modelos que aplicam culturas *in vitro* de queratinócitos. Para isso, trabalhamos com células adquiridas comercialmente e isoladas de doadoras de diferentes faixas etárias, avaliando

características como potencial proliferativo, expressão de marcadores de diferenciação epidermal e capacidade de originar epiderme reconstituída *in vitro*.

A literatura científica não é homogênea quanto ao potencial proliferativo dos queratinócitos com o envelhecimento. Ya-Xian *et al.* (1999) determinou o número de camadas celulares no estrato córneo de 301 voluntários de várias idades, relatando variações que dependem da localização do corpo e fatores genéticos. Baroni *et al.* (2012) não relataram diferenças significativas na espessura das camadas epidérmicas com a idade em 218 mulheres caucasianas. Por sua vez, Waaijer *et al.* (2012) demonstraram que a espessura da epiderme é reduzida com o envelhecimento em 286 indivíduos de descendência holandesa.

Em nossos ensaios in vitro, as células de doadores de diferentes idades foram capazes de originar epidermes reconstituídas, indicando um potencial proliferativo e de diferenciação preservados com o avanço da idade. Entretanto, a expressão dos marcadores moleculares de proliferação e diferenciação foi significativamente maior nas células derivadas de neonatos, em comparação com as demais faixas etárias avaliadas que variavam de 20 a 50 anos, aproximadamente. Tal ocorrência foi observada para a expressão de Ki67, um antigénio nuclear marcador de proliferação, e queratinas, incluindo os tipos 10 e 14, tanto no modelo de cultivo em monocamada quanto na pele reconstituída. Como não foi possível detectar diferenças entre as faixas etárias adultas, ao contrário do que já foi observado in vivo para marcadores como o Ki67 (Nozdrin et al., 2011), nossos resultados sugerem limitações do modelo in vitro para determinados estudos de envelhecimento cutâneo. Como foi possível diferenciar ao menos a expressão dos marcadores nas células de neonatos, acreditamos que os modelos in vitro consigam preservar e evidenciar mudanças moleculares que caracterizam o envelhecimento epidermal. Entretanto, mudanças mais tênues podem ser perdidas ao longo da manutenção das células in vitro, podendo ser este um ponto de atenção para tais modelos de estudo.

O tema de manutenção da atividade de células-tronco epidermais ao longo do envelhecimento é bastante discutido. Há trabalhos relatando ausência de alterações na atividade das células-tronco da epiderme, com mudanças no

controle das chamadas células amplificadoras transientes (Liang et al., 2004; Stern e Bickenbach, 2007; Charruyer et al., 2009). Buscando uma melhor compreensão desta questão, outro ensaio realizado em nosso trabalho com queratinócitos in vitro foi avaliar marcadores de superfície celular capazes de diferenciar populações de células-tronco ou células amplificadoras transientes. Curiosamente, não foram detectadas diferenças guanto à expressão destes marcadores entre as células de doadores de diferentes idades. Novamente, o uso de células cultivadas durante algum período, e não recém-isoladas, pode ter comprometido a detecção de diferenças associadas ao envelhecimento. Kaur et al. (2004) observaram que a expressão dos principais marcadores presentes in vivo pode ser alterada ao longo da manutenção de culturas *in vitro*. Em ensaios anteriores, observamos que é possível obter epidermes reconstituídas mais espessas ao utilizar células recém-isoladas. Além disso, o isolamento de célulastronco de adultos, e até mesmo queratinócitos, é mais complexo. Gragnani et al. (2008) observaram uma relação inversa entre o aumento da idade dos doadores e o número de células isoladas. De maneira geral, percebemos que os modelos in *vitro* podem representar ferramentas promissoras para estudo do envelhecimento epidemal, embora algumas questões, tais como a reprogramação da expressão gênica e a seleção de subpopulações celulares ainda precisam ser mais bem avaliadas.

5. CONCLUSÕES

De forma geral, os resultados encontrados neste trabalho reafirmam a epiderme como um componente ativo da pele, cujas funções biológicas são significativamente afetadas pelo envelhecimento.

Especificamente, pode-se concluir que:

 Alterações possivelmente associadas à desregulação homeostática acometem a epiderme ao longo do envelhecimento, sugerindo uma perda gradativa na capacidade do tecido epidermal de responder a elementos externos que desafiam o equilíbrio cutâneo.

• Apesar de diversas variações, alguns genes demonstraram tendência clara de aumento ou redução contínua ao longo do envelhecimento da epiderme. Dentre eles, foram identificados marcadores com envolvimento na função de barreira, como SPPR2G (*small proline-rich protein 2G*) e o componente de envelope córneo LCE1 (*late cornified envelope 1A*).

• A avaliação global de transcritos associados ao envelhecimento da epiderme humana em amostras de pele fotoexpostas permitiu a identificação de processos moleculares que podem auxiliar no entendimento de características clínicas ou morfológicas. A regulação do gene da actina beta (ACTB), por exemplo, pode estar relacionada à ocorrência de ceratose hiperproliferativa.

 Há diferenças significativas na interpretação do envelhecimento epidermal de acordo com a técnica empregada para amostragem. Em nosso caso, as coletas de fitas adesivas ou de pelos de sobrancelha apontaram para a regulação de processos ou vias biológicas distintas, evidenciando nichos biológicos com particularidades funcionais e moleculares nas regiões folicular ou interfolicular da epiderme.

• Maior capacidade de proliferação e diferenção foram observadas para queratinócitos *in vitro* isolados de doadores neonatos quando comparados a doadores adultos de entre 20 e 50 anos, aproximadamente.

Running title: Overview of epidermal aging

Abstract

As the outer layer of the skin, epidermis plays multiple essential protective roles; the transitory nature of epidermal layers implies a continuous supply of new cells to maintain a multilayered tissue that undergoes permanent homeostasis throughout life. However, like any biological system, epidermis has an imperfect balance. Thus, epidermal homeostasis progressively deteriorates with aging, which is reflected in loss of the ability of the epidermis to give stability to its major molecules and cells, and consequently to preserve its own organizational and functional integrity. The bathtub elegantly illustrates the "modus operandi" of the epidermis, because the model is perfectly compatible with current biological findings: 1) tap flow has been enriched by the boom in epidermal stem cell research – fundamental for a comprehensive view of epidermal renewal dynamics; 2) bath volume has grown with the discovery of molecular pathways involved in epidermal stratification, differentiation, and cell signaling through a complex regulatory network; and finally 3) plug-hole has been refined with the discovery of details on important biochemical and physicochemical properties of the stratum corneum, as well as on its genesis and subsequent desquamation. Furthermore, age-related intrinsic and extrinsic components have considerable effects on epidermal machinery, leading to disturbances in skin physiology and possible impairments in the quality of life of elderly people. This work presents an overview of the structure and function of epidermis, by refilling the old bath model with the results of recent advances to provide an integrative perspective, and discusses the main epidermal changes that come with aging, suggesting new opportunities for future studies and/or possible dermatological therapies.

Introduction

Epidermis – the outer layer of the skin – represents a functional barrier in the control of substances that can be released from or absorbed into the body (Sotoodian and Maibach, 2012) and plays an important role in the prevention of water and nutrient loss, while performing multiple essential protective functions against environmental insults, such as toxins, pathogens, chemicals, pollution, mechanical stress and solar ultraviolet (UV) radiation (Simpson *et al.*, 2011; Ramos-e-Silva and Jacques, 2012). As the most exposed body part, epidermis is also an important indicator of skin health, which has significant psychosocial implications (Farage *et al.*, 2008c and 2010a). Skin imperfections have a negative influence on self-esteem and can cause considerable emotional distress. Outweighing the aesthetic importance, some diseases or disturbances specifically affecting epidermal organization, such as vitiligo or psoriasis, interfere considerably with the quality of life of the patients by causing anxiety, depression, and social withdrawal (Bilgiç *et al.*, 2011; Jobling and Naldi, 2006; Sotoodian and Maibach, 2012).

Although aging is a natural process, it is also a factor that significantly affects epidermal tissue. Over time, cumulative exposures to external aggressors wear down the machinery of the human body, leading to functional deterioration and changes in biological structures. Considering that the population is aging rapidly, the skin is a portal of knowledge on aging, and the body of knowledge is burgeoning on this subject, Farage *et al.* (2010b) organized a comprehensive textbook that covers details in respect to structure and function, cellular and molecular mechanisms, and the latest bioengineering instruments used to assess age-related changes in the skin. As for the epidermis, aging causes disturbances in its barrier function. Aged skin tends to have an overall drier, duller and tired aspect, and is more predisposed to wrinkling. A common clinical sign in the elderly is xerosis – i.e., abnormal dryness of skin (Durai *et al.*, 2008). It is usually a source of discomfort, either because of the unsightly aspect of increased skin flaking or

because of the annoying pruritus, of which excessive dryness is the most common cause in older adults (White-Chu and Reddy, 2011).

Specifically on the subject of aged epidermal permeability barrier, a review by Elias and Ghadially in 2002 focused on the basis of functional abnormalities. Since then, increasing numbers of scientific publications related to the subject have emerged. A search in the Pubmed literature base (www.pubmed.com) using the words "epidermis" and "aging" shows that the total number of citations from 1954 to 2002 was 556, a figure that had almost doubled, to 1176, by the end of 2012. More than looking at recent researches merely from a quantitative perspective, it is important to consider the qualitative approach taken in such works with respect to the technological advances and innovative areas that evolved over the last decade. Some of these developments appeared during the boom in stem cell research (including stem cells present in the skin and particularly in epidermis) (Castilho et al., 2009; Fuchs, 2008); others gave rise to the emergence of new fields derived from cell and molecular biology (such as "omics" and high throughput analyses, development of reliable alternative methods based on 3D reconstructed models, description of new signaling pathways, and others) (Blumenberg, 2012; Boulter et al., 2013; Brohem et al., 2011; Castilho et al., 2009).

This review summarizes recent biological findings and functional mechanisms related to epidermal aging from an integrative perspective, rethinking the bath model as an opportunity to discuss scientific works that have been published since one of the first propositions for the "modus operandi" of epidermis was put forward.

Epidermal structure and bath model

More than a physical structure, epidermis is a highly specialized epithelium that undergoes a continuous renewal process and is characterized by overlapped cells that form a stratified barrier on the surface of the body to protect it against external aggressions and maintain its required balance of fluids and ions. A variety of cell types are found in epidermis: keratinocytes (corresponding to 80-95% of the epidermal cells), melanocytes (that produce melanin for skin pigmentation), Langerhans cells (antigen presenting cells for immunosurveillance), and Merkel cells (capable of synthesizing catecholamines and thought to act as tactile receptors). Four main cell strata are distinguished according to the level of keratinocyte maturation: basal layer (BL; cells with a high proliferative capacity), spinous layer (SL; desmosome-enriched, thorny-looking cells), granular layer (GL; cells abundant in lipid and protein granules), and stratum corneum (SC; dead, enucleated and flattened cells, also called corneocytes, interspersed with intercellular lipids). BL is the inner layer and its proliferative cells are responsible for constant epidermal replenishment. They migrate toward the skin surface, crossing both SL and GL, until their complete differentiation in SC. The process occurs every four weeks throughout the lifetime. In some anatomic regions where skin is especially thick, such as the soles and palms, it is possible to differentiate a fifth layer between SC and GL: the stratum lucidum, designed to help the body handle friction (Brohem et al., 2011; Fuchs and Raghavan, 2002; Simpson et al., 2011).

"Epidermal engine" was the term defined by Marks (1986) in his paper on epidermal complexity and dynamics. The "epidermal bath model" was used as a practical analogy in which the size of the cell population was likened to the bath volume, and the rates of inflow from the tap and outflow from the plughole were taken to resemble epidermopoiesis and desquamation, respectively (Figure 1). Dynamic balance presupposes a perfect reposition system, by which the proliferation of cells is activated inside the epidermis as other cells are lost outside it. The basis of this system is similar to that of homeostasis, defined by O'Neill (1997) as the ability of a living organism to control its internal conditions in spite of fluctuations in the external environment. In terms of energy balance, however, living organisms are not perfect systems, and constant exposure to external insults, associated with a preprogrammed resistance of internal genetic-based components, leads to a continuous systemic degeneration.

Figure 1. Epidermal bath model, originally proposed by Marks (1986). The model consists of three main components: (1) tap, which represents epidermopoiesis or cell renewal that results from constant proliferation in the layer connected to basement membrane (BM); (2) bath volume, which corresponds to the size of epidermal cell population; and (3) plughole, which stands for the desquamation process of continuous corneocyte release due to physical stressors. Keratinocyte flow is indicated by blue arrows, including the direction of their differentiation process, which drives them from the inside to the outside toward the body surface and through different epidermal layers, in the following sequence: basal layer (BL), spinous layer (SL), granular layer (GL) and stratum corneum (SC).

Aging and loss of homeostasis capacity

Aging – a key concept in explaining homeostasis failures during life – is a highly complex biological process involving cumulative changes that affect the ability of the organism to respond adaptively to stress (Gilhar *et al.*, 2004; Kirkwood, 2005). Impact of aging can be perceived in different parts of the organism, where it promotes loss of function and affects the self-adaptive capacity
of the system to maintain optimal internal conditions. Progressive deterioration of the ability of cells and tissues to preserve the stability in some of their biological molecules, such as nucleic acids or proteins, that comes with age also contributes to the functional loss (Garinis *et al.*, 2008; Koga *et al.*, 2011). Overall system failure in controlling homeostasis results from the sum of interdependent occurrences. Since the human body is an integrated system, disturbances in the original function of specific components are expected to reflect on others in a domino effect. Aging leads to physiological and metabolic failures in systems of temperature control, intra- and extracellular ion level regulation (especially for sodium and potassium), and water and hormone balance (Copinschi and Caufriez, 2013; O'Neill, 1997). All these changes may impact the skin.

Elderly seem more susceptible to hypo- or hyperthermia when exposed to thermal stress, which can cause cell death or DNA damage (Anderson *et al.*, 1996; Roti Roti, 2008). Keratinocyte response to hyperthermia shows intriguing results, such as the development of heat tolerance and UVB resistance (Kane and Maytin, 1995; Maytin, 1992; Maytin *et al.*, 1993 and 1994), or apoptosis induction and micronuclei formation (Hintzsche *et al.*, 2012; Wang *et al.*, 2009). However different the experimental designs, the activation of cellular anti-stress systems is a common feature, sometimes marked by the expression of heat shock proteins (HSP). Independently of protective or damaging responses, any deviation in physiological patterns leads the cells to turn on warning signals mediated by consistent epidermal mechanisms of tissue recovery. Still, according to Maytin (1992), changes in the expression of many stress-inducible genes often occur under conditions ultimately lethal to the cells, calling into question their adaptive significance.

Regarding hormonal imbalance with aging, postmenopausal women usually have reduced levels of estrogens; this accelerates the decline in the appearance of the skin by affecting several of its functions, such as hair growth and the pigmentation, vascularity, elasticity, and water-holding capacity of the skin (Shu and Maibach, 2011; Verdier-Sévrain *et al.*, 2006; Zouboulis *et al.*, 2007). In addition, skin collagen content decreases at a rate of 2% per year (Brincat *et al.*,

1987; Shah and Maibach, 2001). In men, aging-induced reductions in androgen levels correlate to decreased skin thickness and body hair (Wespes and Schulman, 2002; Zouboulis *et al.*, 2007). Such findings substantiate the fact that age-related systemic homeostasis failures cause significant structural changes in the skin and diminish its capability to regenerate its original, or younger, organization.

Homeostasis presupposes the need of an organism to sense and respond to environmental changes by setting in motion mechanisms to restore its previous state of balance (O'Neill, 1997). Skin plays a fundamental role in the interaction with the external environment: it acts as a selective barrier and a major sensory organ of the body. Consequently, aged skin might have a cumulative impact on the entire aged organism, since its diminished internal capacity to adjust to environmental changes is further reduced by a compromised protective barrier that may fail to capture outside signals (Benedetto, 1998; Dufour and Candas, 2007; Farage et al., 2008b; Farage et al., 2009) (Figure 2). Epidermis, in particular, is the first line of contact with the surroundings, which increases the significance of a better understanding of the impacts of aging on this element of the skin (De Luca and Valacchi, 2010). Denda's group, a specialized team working on epidermal issues, hypothesizes that an information-processing function may exist in the epidermis, particularly because of its ectoderm-derived origin – the same as the nervous system - and also because of the expression of neurotransmitter receptors in different cells (Boulais and Misery, 2008; Denda and Tsutsumi, 2011). Basically, Merkel cells form an enigmatic skin cell population, found at the epidermal/dermal border, synaptic-connected with sensory terminals. Merkel cells are proposed to be mechanotransducers related to light touch responses. However, exactly how Merkel cells transduce mechanical signals remains unknown (Maricich et al., 2009; Reed-Geaghan and Maricich, 2011). A recent review suggested that the acid-sensing ion channels (ASICs), expressed in Merkel cellneurite complexes, might be a possible component that would help to elucidate mechanotransduction pathways in the skin (Chen and Wong, 2013).

Figure 2. Epidermal mechanisms for capturing of external signals and regulation of homeostasis. (1) An important component of the ability of the organism to sense external environment, it allows different signals to be detected by epidermis, including temperature variations, mechanical stress and chemical stimuli. (2) Transient receptor potential channels (TRP) are ionic channels located in the membrane of free nerve endings and keratinocytes, and constitute an epidermal sensitive mechanism. Primarily related but not restricted to thermal oscillations, various environmental factors are sensed by TRP receptors, and their signals are transferred to peripheral sensory nerve fibers. (3) Merkel receptors are described as part of the cutaneous sensory system, composed of Merkel cells (containing numerous neuropeptides inside dense core neurosecretory granules) and sensory afferents (with structures known as tactile discs), which are connected to periphery nerve fibers. Exact way by which Merkel cells work is still object of debate, but some authors consider them as excitable neurone-like cells that may respond to various stimuli, and recent findings proved their essential contribution to light touch responses. (4) In view of the crucial role of epidermis as a sensory tissue, epidermal homeostasis has direct implications in the overall homeostasis of the organism. Aging affects the epidermal balance between cell renewal and desquamation, much as it affects several internal organs, which experience loss of functional properties. Thus, reduced ability of aged epidermis to deploy best internal defenses against environmental aggressors may be further compounded by its diminished ability to sense external signals. This extends the cumulative impact of epidermal aging to homeostasis of the whole organism.

In addition to terminal sensory nerves and Merkel cells, keratinocytes have also been recently described as sensitive cells. Recent studies have been specifically targeted to determine the sensitive properties of keratinocytes, and the superfamily of transient receptor potential channels (TRPs) has emerged (Denda and Tsutsumi, 2011). TRPs are non-selective cation channels expressed throughout the body and regulated by stimuli; they are subdivided into seven families: TRPA (ankyrin), TRPC (canonical), TRPM (melastatin), TRPML (mucolipin), TRPN (no mechanoreceptor potential C), TRPP (polycystin), and TRPV (vanilloid) (Fernandes et al., 2012; Steinhoff and Bíró, 2009). Since TRPV1 was identified in epidermal keratinocytes, the involvement of TRP in epidermal tissue has significantly changed (Denda et al., 2001b). After TRPV1, TRPV3 was found to mediate a cell autonomous response in keratinocytes upon exposure to heat (Peier et al. 2002). Subsequently, other channels have been shown to play a temperature regulatory role in keratinocytes, such as TRPV-4 (sensitive to heat) and TRPA1 (sensitive to cold) (Atoyan *et al.*, 2009; Denda *et al.*, 2007; Fernandes et al., 2012; Lee and Caterina, 2005). Temperature-sensitive ion channels affect other functions and skin processes as well, including cellular differentiation and flow reinforcement of cell proliferation. water control. junctions and mechanosensory properties (Akazawa et al., 2013; Bíró and Kovács, 2009; Denda and Tsutsumi, 2011; O'Neil and Heller, 2005; Steinhoff and Bíró, 2009;).

How skin undergoes aging and epidermal organization impact

Aging is a complex and multifactorial phenomenon, composed of intrinsic and extrinsic factors, defined respectively by individual genetic constitution and external insults. In humans, aging is said to be directly influenced by lifestyle and, according to Farage *et al.* (2007 and 2008a), the intrinsic rate of skin aging in any individual can also be dramatically influenced by personal, socioeconomic and environmental factors. Nevertheless, as the lifetime of an individual unfolds, a particular set of genetically programmed events drive the changes that take place in all tissues and lead to the aging of the whole organism (Makrantonaki *et al.*, 2012; Zouboulis and Makrantonaki, 2011). Aging skin undergoes progressive degenerative changes; constant exposure of the skin to environmental aggressors contributes to accelerating or intensifying the process (Farage et al., 2009). According to the micro-inflammatory model, UV radiation skin exposure promotes migration of macrophages and production of free radicals affecting resident cells, such as fibroblasts or keratinocytes. Neo-synthesis of adhesion molecules is stimulated in endothelial cells by recruiting new inflammatory cells, thus closing the cycle of self-maintained micro-inflammation, which results in the disruption of skin tissue and the ensuing loss of volume and elasticity (Giacomoni and Rein, 2004). From the clinical viewpoint, skin aging is characterized by wrinkling, flabbiness, increased fragility, blister formation, impaired wound healing, dryness, pigmentation changes, and increased risk of cancer (Farage et al., 2007, 2008b and 2009). Deeper wrinkles and a leathery appearance result from extensive sunlight exposure (Scharffetter-Kochanek et al., 2000). Clinical signs reflect internal and structural changes extensively reviewed by Waller and Maibach (2005) and 2006), including diminished blood flow, reduced thickness of different skin layers, disorganized collagen and elastic fiber patterns, reduced activity of enzymes involved in post-translational modification processes, protein aggregate formation, changes in deposition of glycosaminoglycans (GAGs) which then tend to interact less with water molecules, and changes in the lipid content of the skin.

Even with the numerous dermal aging studies based mainly on the supportive function and fiber-enriched structure of the dermis, the epidermis has recently been receiving more attention. Although epidermal machinery becomes less efficient with age, the balance between cell production and cell loss may change over the entire lifetime (Gilhar *et al.*, 2004). Several studies suggest that, much more than just undergoing minor functional abnormalities, the epidermal structure in fact suffers multiple impacts from intrinsic and extrinsic aging (Table 1). Many other mechanisms have been identified since the 1980's to complement the epidermal bath model, and many studies explain the more significant changes that affect the aging epidermis. Discovery of new molecules and the identification of new biological functions make it important to rethink and complement the three

main steps of the epidermal bath model in light of recent advances in cell and molecular biology.

Affected characteristic	Observed effect of aging	Skin condition*	Reference
Epidermal surface	Increase in number of pores	PP	Rawlings, 2006
	Deterioration of fine reticular patterning in the SC surface	PP/PE	Shekar <i>et al.,</i> 2005
	Deteriorated surface appearance and weakening in the adhesion of keratinocytes to SC, especially in photoaging	PP/PE	Chu and Kollias, 2011
	Change in the rhomboidal epidermal furrow pattern to a linear appearance	PE	Longo <i>et al.,</i> 2013
Epidermal thickness	Decrease in thickness of viable cellular epidermis, without changes in SC	PP	Lock-Andersen <i>et</i> al., 1997
	Thinning epidermis by 10-50% between 30 and 80 years	PP	Makrantonaki and Zouboulis, 2007
	SL atrophy	PP	Zouboulis and Makrantonaki, 2011
	Constant mean epidermal thickness from 6-84 years in sun-exposed and protected skin, showing thicker epidermis in facial in comparison with abdominal skin	PP/PE	El-Domyati <i>et al.,</i> 2002
	Decrease in epidermal thickness and in the amount of viable cell layers from 17 to 81 years	PP/PE	Levakov <i>et al.,</i> 2012
	Thickening of the SC with faulty degradation of desmosomes, dehydration and microfissures	PE	Leyden, 2001
	Reduced epidermal thickness by 30% in in individuals older than 65 years, despite a slight increase in middle-aged subjects	PE	Longo <i>et al.</i> , 2013

Table 1. Structural changes in epidermis with aging.

Epidermal shrinkage	Decrease in epidermal shrinkage by 22% in superficial layers and 6% in the lower epidermis	PP	Moragas <i>et al.,</i> 1993
Dermo-epidermal junction organization	Flattening of the dermo-epidermal junction, with 36.3% decrease in the rete peg-related roughness index, mainly between 40 and 60 years	PP	Moragas <i>et al.,</i> 1993
	Flattening of dermal-epidermal junction from 17 to 81 years	PP/PE	Levakov <i>et al.,</i> 2012
	Reduced collagen type VII containing anchoring fibrils, while collagen IV might be also degraded	PE	Scharffetter- Kochanek <i>et al.,</i> 2000
Cellular morphology and distribution	Expanded intercellular space throughout epidermis	PP	Minematsu <i>et al.,</i> 2011
	Increased heterogeneity in basal cell size, decreased mitotic activity, increased duration of cell cycle and migration time of keratinocytes, slow replacement of lipids in the SC, decrease and heterogeneity of melanocytes, decrease of Langerhans cells	PP	Zouboulis and Makrantonaki, 2011
	Increase in the amount of keratohyalin granules from 17 to 81 years	PP/PE	Levakov <i>et al.,</i> 2012
	Appearance of "sunburn" cells (keratinocyte apoptotic cells), DNA damage to basal keratinocytes, increased numbers of melanocytes and melanocytic hyperplasia, and Langerhans cell depletion	PE	Leyden, 2001
	Impaired adhesion, proliferation and differentiation of keratinocytes	PE	Makrantonaki and Zouboulis, 2007
	Presence of irregularly shaped keratinocytes, irregular honeycomb pattern and areas with unevenly distributed pigmentation	PE	Longo <i>et al.,</i> 2013

Opening the tap flow: cell renewal dynamics in BL

The first step illustrated in the epidermal bath model (Figure 1) refers to tap flow, focused on the cell renewal dynamics that occurs in the BL. A massive

amount of recent studies related to epidermal stem cells accounts for the elucidation of epidermopoietic regulation. The BL contains a heterogeneous proliferative cell population and also cells committed to terminal differentiation (Fuchs, 2008). Basically, tissue renewal depends on epidermal stem cells with a high-proliferation capacity and a low terminal-differentiation probability. Characteristically, such stem cells express relatively higher levels of y-catenin and β 1 integrins and lower levels of E-cadherin and β -catenin than other basal keratinocytes (Molès and Watt, 1997). Proliferative populations also express keratin 5 (K5) and K14, as well as p63, an important molecule working as a gatekeeper of proliferation in epithelial stem cells (Fuchs, 2008; Senoo et al., 2007). In addition, many studies recognize that the stem cells engender transitamplifying cells designed to undergo terminal differentiation after a few rounds of division, about five times before reducing its adhesiveness to the underlying BM and delaminating (Fuchs, 2008). Although there are heterogeneous concepts about the exact function of proliferating cells in the BL, as well as about the epidermal proliferative unit organization, a consensus has, nevertheless, been reached about BM as a niche for epidermal progenitors, and displacement is likely to play a significant role in cell fate (Ray and Lechler, 2011). In BL, a fine regulation occurs to maintain the renewal cycle of the epidermis, with two main classes of cell division - symmetric and asymmetric - and different possibilities of spindle orientation (Figure 3).

Occurrence of asymmetrical divisions provides a different view of how a basal stem cell and a committed cell might arise. In the first of the studies on this subject, epidermal stem cells were shown to shift from a lateral to a more perpendicular spindle orientation to undergo asymmetrical divisions, which account for 70% of total basal cell mitoses, while 30% of the cell mitoses remained symmetric (Lechler and Fuchs, 2005). Clayton *et al.* (2007) demonstrated that most asymmetrical divisions in epidermis leave both daughter cells adhering to BM, with the committed cells inheriting a stronger Notch signal as a key transcriptional determinant of the spinous cell fate. An additional consideration is that distinct patterns of cell division and proliferation can operate in different life

stages. During early stages of embryonic skin development, most cell divisions are symmetric and parallel to BM, which ensures the growth of the surface with the epithelium as a single layer. During epidermal stratification, the majority of cell divisions become asymmetric, such that the mitotic spindle aligns perpendicularly to the BM in order to allow the quick development of suprabasal cells, which differentiate terminally and form stratified layers. In adult skin, predominant plane of asymmetric divisions is parallel to the BM, such that one daughter cell remains a stem cell, while the other is committed to terminal differentiation and probably undergoes delamination to reach the suprabasal layers (Blanpain and Fuchs, 2009).

Figure 3. Epidermal cell renewal. Epidermopoiesis depends on proliferative cells present in the basal layer (BL). Stem cells (STC) generate transit amplifying cells (TAC), which have been postulated to divide four to five times, and/or spinous cells (SPC) committed to terminal differentiation. There are two main classifications for cell divisions: (1) symmetric, when both daughters adopt the same fate, or (2) asymmetric, when there is unequal segregation of a cell fate determinant, or when one of the daughters strays from the STC niche, resulting in daughters with distinct fates. The cell division plane can be parallel or perpendicular to the basement membrane

(BM). When spinous cells committed to terminal differentiation are originated in contact with the BM, a reduction of the adhesiveness to the substratum is needed for delamination (blue arrows), which allows cell migration and differentiation.

Specific markers have been identified as important controllers for the orientation of the division in basal cells; examples of such markers are the differential segregation of integrins, growth factor receptors, and the more recently described apical positioning of Par complex associated with the mInsc/LGN/NuMA complex for the anchorage of dynein and microtubules (Blanpain and Fuchs, 2009; Ray and Lechler, 2011). Recent studies on the maintenance of proper balance between stem cell quiescence and proliferation over the lifetime of the organism uncovered new regulatory networks for the control of the proliferation and terminal differentiation of epidermal stem cells, such as the regulation of Yap (Yesassociated protein) – a transcriptional effector of Hippo growth pathway – by the adherens junction component α -catenin (Flores and Halder, 2011; Schlegelmilch *et al.*, 2011; Zhang *et al.*, 2011).

Regarding the effect of aging under the conditions imposed by the dynamics of cell renewal in BL, thinning of the epidermis and its diminished self-healing capacity were at first associated with decreasing numbers of, or functional changes in, epidermal stem cells (Winter and Bickenbach, 2009). But this topic remains under discussion in the scientific community. Giangreco et al. (2010) observed, especially in subjects over 60 years, a significant reduction in rete ridge height and basal cell density, as well as a lower expression of two markers of human interfollicular epidermal stem cells: melanoma chondroitin sulfate proteoglycan (MCSP) and β 1 integrins. There is a decline in the regenerative potential of tissue with age, which could be ascribed to intrinsic aging of stem cells and/or of the microenvironment of the tissue lodging the stem cells (Rando, 2006). Using a murine model, Liang and coworkers (2004) demonstrated that aged and young stem cells show similar plasticity response when placed in the developmental environment of a blastocyst, as well as similar gene and protein expression profiles. Stern and Bickenbach (2007) did not find significant differences in the epidermal stem cell number per unit area of the epidermis of footpads of young

and old adult mice. Moreover, they found similar characteristics in cell cultures from each of the two groups, including the same lengths for the telomeres and similar results for gene expressions related to cell cycling, apoptosis, stress response, and stem cell dynamics (no differences in the 422 tested genes, when comparing freshly isolated young and old epidermal stem cells). These results led the authors to conclude that epidermal stem cells are resistant to cellular aging. Both studies conducted by Liang et al. (2004) and Stern and Bickenbach (2007), suggest that the ability of stem cells to respond to environmental influences might not diminish with age. In support of this hypothesis, Giangreco and coworkers (2008) showed that epidermal stem cells are retained by the organism throughout its lifetime despite significant age-associated changes in dermal thickness, epidermal proliferation, and peripheral immune cell abundance, suggesting that local environmental or dermal factors, rather than stem-cell-intrinsic factors, influence skin aging. How stem cells preserve this capacity throughout lifetime remains unclear, but it may be due to an intrinsic set of stem cell genes, which are to be determined. In a study with stem cells from the bulge of skin hair follicles of young and aged human skin, the results found by Rittié et al. (2009) were similar to those observed in mice: aging did not alter the expression or location of hair follicle stem cell markers, and there were no significant differences in hair follicle density or bulge cell numbers between young and aged human scalp skin. Regarding the mechanisms of stem cell retention in the skin, the authors noted that hedgehog (Hh) signaling is activated in human bulge cells in vivo and down-regulated in differentiated hair follicule keratinocytes, both in young and aged skin. Some controversial results notwithstanding, increased telomerase expression and activity in epidermal basal cells may represent another possible mechanism for preserving the stem cell potential (Buckingham and Klingelhutz, 2011).

Even so, if the number and functionality of epidermal stem cells are not affected by aging, the question remains: what causes the structural changes observed in the elderly epidermis. Transit amplifying cells seem to play a key part in the answer. Even the authors, who did not detect differences in stem cells of the young and old, were able to identify some particularities in the characteristics of

transit amplifying cells (Giangreco et al., 2008; Liang et al., 2004; Stern and Bickenbach, 2007). Charruyer et al. (2009) demonstrated that transit amplifying cell frequency and cell cycle kinetics are altered in the aged epidermis. They used in vivo transplantation of green fluorescent protein-labeled epidermal cells to evaluate the formation of replicating units (RUs) from stem cells (long-term RUs, survived more than 9 weeks) or transit amplifying cells (short-term RUs, lost before 9 weeks). No differences were observed in the number of long-term RUs when comparing young and old keratinocytes, which indicated that the number of stem cells is relatively constant in aged and young epidermis. However, fewer short-term RUs were found after transplantation of young cells in comparison with transplantation of old cells, which seemed contradictory. The answer for this intriguing question was provided by a complementary discovery: the increased cell cycle duration in the aged cells. In their comments on the study, Winter and Bickenbach (2009) compared the findings described by Charruyer et al. (2009) to a crowded freeway: when the vehicles travel at lower speeds, overall result is more vehicles on the road at any given time, which could be an analogy to more transit amplifying cells in the aged epidermis. Increased number of transit amplifying cells in the aged epidermis might be a means of compensating their decreasing activity with age. Although the number of long-term RUs containing stem cells is similar in young and in aged epidermis, aging skin heals more slowly or is thinner because of a reduction in the efficiency of regeneration from transit amplifying cells.

When evaluating the effect of photoaging in epidermal proliferative populations, Kwon *et al.* (2008) found less keratinocyte stem cells and more transit amplifying cells in photoaged than in chronologically aged skin. In keratinocyte cultures, replicative senescence is a gradual process that occurs only when all stem cells have completed their clonal evolution and give rise to terminal transit amplifying cells, named paraclones. Cordisco and coworkers (2010) observed that human keratinocyte replicative senescence is associated with a progressive increase in the expression of p16^{INK4a}, whose expression is also detectable in primary keratinocytes from elderly subjects; p16^{INK4a} is in particular constantly present in individuals of more than 70 years of age. Remarkably, first-passage

keratinocyte cultures show a strong positive correlation between stem cell depletion and early p16^{INK4a} expression, indicating the presence of senescent cells in the epidermis from old donors. Presence of higher paraclone percentages and p16^{INK4a} levels in keratinocyte cultures from old photoexposed skin, as compared with non-photoexposed skin, indicated that chronic UV exposure contributes to keratinocyte senescence. Moreover, the authors assigned the downregulation of Bmi-1, a p16^{INK4a} repressor, a key role in the enforcement of primary human keratinocyte aging.

Although many studies corroborate the importance of transit amplifying cells, some authors understand that these cells might not be required for epidermal homeostasis; they favor, instead, a single proliferative progenitor cell population to sustain epithelial renewal (Clayton et al., 2007). To clarify this issue and prove existence of transit amplifying cells, Mascré et al. (2012) conducted an elegant study based on the application of two Cre recombinase-oestrogen receptor (Cre-ER) transgenic mice that target interfollicular epidermis progenitors: Cre-ER under the control of the K14 promoter (K14-Cre-ER) and Cre-ER under the control of the involucrin promoter (Inv-Cre-ER); both allowing lineage tracing experiments by analyses of tamoxifen-induced fluorescence. Inv-Cre-ER targets committed progenitors (or transit amplifying cells) while K14-Cre-ER targets long-lived stem cells. Pattern of growth of individual clones targeted by the Inv-Cre-ER indicated that, following the divisions of committed progenitors (about 1 division per week), 80% resulted in asymmetric fate (leading to one dividing and one differentiated cell) with the remainder leading to symmetric duplication or differentiation with approximately equal probability. Dynamics of the clones targeted by K14-Cre-ER followed a quite different pattern, with an initial abrupt expansion followed by deceleration over the first few weeks, which indicates that, after division, stem cells re-enter a quiescent phase whereas their progeny go on to proliferate and differentiate. With a slower division rate (4 to 6 divisions per year), $80 \pm 10\%$ of stem cell divisions result in asymmetric fate (one stem cell and one committed progenitor cell), whereas the remaining divisions are equally balanced between stem cell duplication and symmetrical differentiation into two committed progenitor

cells (Figure 3). Mascré *et al.* (2012) also performed a molecular characterization of the cells, proving the existence, as much as the hierarchical organization and proliferation dynamics, of two distinct types of progenitors involved in epidermal homeostasis and repair.

Even without characterizing different progenitor cell lines, Doles and coworker (2012) showed changes in hair follicle stem cells during skin aging; such changes included increased cell numbers, decreased cell function, and an inability of cells to tolerate stress. This study shows that aging epidermis plays a part in the disruption of cytokine and stem cell homeostasis; this is characterized by an imbalance in the epidermal Jak-Stat signaling, which could easily be adjusted to fit the micro-inflammatory model (Giacomoni and Rein, 2004). Decline in epidermal functionality was interpreted as a mechanism for suppression of tumors that might occur with age. Castilho et al. (2009) used a murine transgenic model to evaluate the consequences of persistently expressing Wnt1 on epidermal stem cells. Rapid growth of the hair follicles caused epithelial cell senescence, disappearance of the epidermal stem cell compartment by the persistent activation of mTOR, and progressive hair loss. While the exhaustion of stem cells may act as a protective mechanism, helping to maintain the genetic integrity of the stem cell population and suppressing tumor formation, persistent activation of mTOR may contribute to cell senescence and, consequently, accelerate aging. Absence of the vitamin D receptor also leads to a reduction in the number of keratinocyte stem cells and impair their function, both *in vivo* and *in vitro*, disturbing the cyclic regeneration of the hair follicle (Luderer and Demay, 2010). Some authors believe that the aginginduced delay in epidermal turnover is related to a decrease in the energy metabolism of epidermal basal cells, suggesting that adenosine 5'-monophosphate (AMP) may accelerate the epidermal turnover delayed by aging (Furukawa et al., 2008). Janich et al. (2011) described a circadian molecular clock in a murine model that creates epidermal stem cell heterogeneity, with coexisting populations of cells at opposite phases of the clock, like dormancy and activation. Core clock protein aryl hydrocarbon receptor nuclear translocator-like (Arntl or Bmal1) modulates the expression of stem cell regulatory genes in an oscillatory manner, to create

populations that are either predisposed or less prone to activation. Janich *et al.* (2011) also found that stem cell arrhythmia can lead to premature epidermal aging.

Most studies on the source of epidermal renewal focus the cellular properties of keratinocytes in BL, but other cells types and the supportive structure of BM also seem affected. Proliferative cells must be maintained in a specific microenvironment to preserve renewal potential. Therefore, age-associated effects of the structural organization of this niche may impact the maintenance of proliferative cells over life. Relatively high incidence of anti-BM antibodies observed in serum samples from elderly subjects exemplifies this and, in fact, highlights occurrence of a specific immune defect in elderly individuals; this probably contributes to the reduction of the rete ridge height of aged epidermis, which, in turn, could lead to a decreasing exchange of nutrients between the epidermis and dermis (Hachisuka *et al.*, 1996). BM of sun-exposed skin becomes damaged and multilayered, and partly disrupted in comparison with the BM of sun-protected skin; BM fragmentation includes the participation of matrix metalloproteinases (MMPs) and plasmin (Amano, 2009).

As for the different proliferative cells types in epidermal BL, Steingrímsson *et al.* (2005) reviewed the subject of melanocyte stem cells and their impact on hair graying, and discussed importance of paired box 3 (Pax3) transcription factor and of microphthalmia-associated transcription factor (Mitf) as key molecules that help to regulate the balance between maintenance and differentiation of melanocyte stem cells. Pax3 works simultaneously to initiate a melanogenic cascade while acting downstream to prevent terminal differentiation. Pax3 activates Mitf expression and at the same time prevents Mitf from activating downstream genes, by competing for enhancer occupancy. Thus, Mitf accumulates until the Pax3-mediated repression is relieved by external stimuli, when the cellular dormant state is broken and differentiation occurs rapidly (Lang *et al.*, 2005). Using the Mitf presence as a typical marker of proliferative melanocytes, Nishimura *et al.* (2005) evaluated the presence of these cells in aging human hair follicles and identified Bcl-2 as a critical molecule for the preservation of melanocyte stem cells were

abundant in follicles from young (20-30 year-old) subjects, which represented 2 to 3% of the total basal keratinocytes in the bulge area, the numbers of melanocyte stem cells were lower in middle-age (40-60 year-old) individuals and absent in most hair follicles of old (70-90 year-old) subjects. Briefly, there is a loss of melanocyte stem cells with age, which temporally precedes loss of differentiated melanocytes in hair matrix.

Describing bath volume: differentiation and signaling mechanisms

Bath Volume represents the second step of the epidermal bath model that is here refilled in detail (Figure 1). Several molecular pathways are involved in regulation of processes creating the stratified epidermal structure. The multilayer organization contains cells with different profiles, which go through a course of continuous differentiation that is governed by a complex network of signaling mechanisms. As such, epidermal bath volume represents a complex and integrated biological system to be explored especially in regard to dynamic changes related to aging (Figure 4).

Calcium is a good example of ions involved in the control of epidermal structure and functionality. Calcium is differentially distributed among cell layers, as an essential element for keratinocyte differentiation, and for maintaining skin barrier homeostasis (Elias *et al.*, 2002). The distribution of calcium in the epidermis varies with age (Denda *et al.* 2003). In young and healthy skin, there is a calcium gradient characterized by low concentration levels in inner layers, such as BL and SL, and by an increasing availability of extra and intracellular calcium, which is reached at its highest levels of concentration in GL. In skin samples of older individuals, however, calcium is distributed equally among all epidermal layers, without forming the gradients observed in young skin (Denda *et al.* 2003). Although direct evidence for this difference in calcium distribution is lacking, it is probably related to structural changes and clinical disorders that affect aged epidermis.

KERATINOCYTES changes in the molecular mechanisms related to maintenance and renewal capacity of proliferator cells (stem cells and/or transit amplifying cells) reduced capacity of response to external signals reduced presence of monosaccharides at the cell surface decrease in specific polysaccharides content, such as HA and GAG accumulation of advanced glycation end products •impaired removal of pyrimidine dimers and alternative splicing for elastin induced by radiation decreased synthesis of lipids •reduced expression and/or activity of molecular markers related to proliferation (Ki-67, HSP-27), immunity (CD1d, TLR3), scavenging of damaged proteins (20S proteasome), hormonal response (MC-1R, MC-2R, MOR-1), signaling (II-1α, TNF-α, RACK-1), hydration (AQP3), structure (K33A, K34, KAP4, ECM1), epigenetic control (Bmi-1), apoptosis (Bcl-2) •increased expression and/or activity of molecular markers related to ionic channels (TRPV1), hormonal response (POMC), signaling (IL-1RII, Smad7, S100A8), inhibitory elements of epidermal renewal (Flil), structure (ECM1 in photoaging), apoptosis (Fas, FasL, p53)

OTHER EPIDERMAL CELLS

- reduced number of melanocyte stem cells in hair follicles
- reduced number of differentiated melanocytes, Langerhans cells and Merkel cell-neurite complexes
- impaired Langerhans cells capacity to induce T cell priming

EXTRACELLULAR MATRIX

- altered structure of BM
- impaired calcium gradient
- decreased total content of lipids
 impaired acidification and secretion
- of antimicrobial peptides in the SC
- increased NMFs content in the SC
- increased desquamation by higher degradation of corneodesmosomes

Figure 4. Refilling bath volume with the major cell and molecular changes involved in epidermal aging. Several mechanisms and pathways describe the effects of aging on epidermis. The vast majority of literature focuses on keratinocyte-related changes, but investigations of other epidermal cells and of the epidermal extracellular matrix organization have also yielded interesting findings. AQP3 (aquaporin 3), Bcl-2 (apoptosis protein B-cell lymphoma 2), BM (basement membrane), Bmi-1 (polycomb ring finger oncogene BMi-1), CD1d (cluster of differentiation 1d), ECM1 (extracellular matrix protein 1), Fas (cluster of differentiation 95), FasL (cluster of differentiation 95 ligand), Flil (flightless 1), GAG (glycosaminoglycan), HA (hyaluronic acid), HSP-27 (heat shock protein 27), Il-1 α (interleukin 1 α), IL-1RII (interleukin 1 receptor type II), K33 (keratin 33), K34 (keratin 34), KAP4 (keratin-associated proteins group 4), Ki-67 (nuclear protein Ki-67), MC-1R (melanocortin receptor 1), MC-2R (melanocortin receptor 2), MOR-1 (μ -opiate receptor 1), NMFs (natural moisturizing factors), p53 (protein 53), POMC (pro-opiomelanocortin), RACK-1 (receptor for activated C kinase 1), Smad7 (intracellular protein mothers against decapentaplegic homolog 7), S100A8 (S100 calcium binding protein 8), SC (stratum corneum), TLR3 (toll-like receptor 3), TNF- α (tumor necrosis factor α), TRPV1 (transient receptor potential cation channel subfamily V member 1).

Using a mouse model, Denda *et al.* (2001a) showed that the skin surface potential is affected by the ion flow between the outside and the inside of

keratinocytes. When calcium or magnesium ions move toward the bottom of the epidermis, skin surface potential becomes negative. Whether potential itself has a role in the epidermal function requires investigation, but it has already been reported to induce keratinocyte migration, accelerate wound healing, and influence skin metabolism or homeostasis (Denda et al., 2001a; Nuccitelli, 2003; Sheridan et al., 1996; Weiss et al., 1990). Thus, an inadequate calcium distribution in aged epidermis may contribute to damage the regeneration capacity of the skin – a typical clinical sign in elderly. Another consequence of the altered calcium gradation in epidermis of older subjects is an increase in exocytosis of lamellar bodies (Menon et al., 1994). Lamellar body secretion and lipid structure is abnormal in the epidermis of patients with Netherton syndrome, a skin disorder characterized by chronic inflammation and universal pruritus (Fartasch et al., 2009). Pruritus is common in older adults and possibly associated with changes in the nerve fibers of aged skin. TRPV1, an ion channel permeable to calcium expressed in keratinocytes and free epidermal nerve endings, has recently been reported to be increasingly expressed under conditions of intrinsic aging and photoaging (Lee et al., 2009a; Lee et al., 2012). While increased TRPV1 expression in nerve fibers in aged skin suggests an important role of this ion channel in the pathophysiology of itchy skin in elderly subjects, it also points to a possible cause for the age-disrupted epidermal calcium gradient. Until now, the few publications in this field do not provide a robust model for ion dynamics at the cellular level of aged epidermis; an overall dysfunction in pumps, ion channels or ionotropic receptors, however, might be a reliable candidate to explain altered dispersion of calcium and consequent morphologic and functional abnormalities seen in older individuals (Denda et al., 2003). Since monosaccharides are capable of regulating calcium pump function, it is possible that abnormal distribution of calcium in aged epidermis may be related to the reduced presence of monosaccharides at the surface of epidermal cells (Georgiou et al., 2005; González Flecha et al., 1999; Tengholm et al., 2001). A study analyzing the influence of age on the carbohydrate residue composition of keratinocyte plasma membranes in human sun-protected skin detected no changes in the concentration

and distribution of β -D-galactose, D-galactose- β -(1,3 N-acetylo-D-galactosamine), β -(1,4-D-N-acetylo- β D-glucosamine) and α -D-N-acetylo-D-galactosamine at the cell surface with age, while the expression of α -D-mannose, α -D-glucose and α -Lfucose at the cell surface reveals marked reductions in the groups of people over 50 years of age (Georgiou *et al.*, 2005).

Other findings point to molecules or mechanisms related to increased difficulty of the epidermis to sense external signs, protect the interior of the body and/or eliminate damage caused by aggressors, when comparing samples from individuals of different age groups. Overall, the effect of increasing age on keratinocyte response both to exogenous and endogenous mitogens is striking and marked by a significant decrease in mitogenic responsiveness and colony-forming potential (Gilchrest and Yaar, 1992). Ki-67 is a nuclear protein that is associated with, and may be necessary for, cellular proliferation. Staining of Ki-67, an indication of proliferation index in young epidermis, was approximately twice as strong in younger than in older epidermis (Gilhar et al., 2004). HSP-27 decreases in the epidermis with age, which might impair keratinocyte differentiation (Jonak et al., 2006; Jonak et al., 2011). A gradually decreasing level of CD1d protein production in human epidermis with age was also reported, suggesting a lowering of the immune response. CD1d belongs to a family of antigen-presenting molecules that are structurally related to the classic major histocompatibility complex (MHC) class I proteins; in normal human skin, CD1d protein production is confined to keratinocytes immediately beneath the lipid-rich stratum corneum (Adly et al., 2006). The 20S proteasome shows an age-related decline in activity that is associated with changes in its subunits, suggesting impairment of the epidermal proteolytic system, which should be responsible for the removal of abnormal and oxidatively damaged proteins (Bulteau et al., 2000).

A key element of innate protection is the recognition of pathogen-associated molecular patterns (PAMPs) by Toll-like receptors (TLRs) expressed by several cell types, including skin keratinocytes. TLR3, specifically related to antiviral defense, exhibited enormous differences in the magnitude of expression and function, including enhanced secretion of cytokines (such as CXCL8/IL8,

CXCL10/IP-10 and TNF- α) in epidermal keratinocytes, before and after birth, when compared with adults, suggesting the existence of age-specific responses (Iram et al., 2012). In assessing the ability of keratinocytes to respond to hormonal stimulation according to the aging status, Pain et al. (2010) studied proopiomelanocortin (POMC) and related receptors, such as melanocortin receptors 2 (MC-2R and MC-1R) and µ-opiate receptor 1 (MOR-1) for and 1 adrenocorticotrophic hormone (ACTH), α -melanocyte stimulating hormone (α -MSH), and β -endorphin, respectively. Gene and protein expression of MC-1R, MC-2R and MOR-1 dramatically decreased with age, whereas POMC increased fivefold. Results were more significant around 50 years of age, which could include menopausal women, suggesting a significant contribution of menopause to changes in epidermal physiology with aging. Ye et al. (2002) addressed the hypothesis that cytokine dysregulation may cause permeability barrier abnormality in aged epidermis, mainly as a result of altered expression of interleukin 1 (IL-1) family of cytokines and receptors, which could help to explain decreasing mitogenesis and lipid synthesis with epidermal aging. Gene and protein expression of aquaporin 3 (AQP3), involved in the transport of water and glycerol to hydrate the skin, decreases with increasing age in human epidermis and isolated keratinocytes; this decrease is probably involved in the development of xerosis (Li et al., 2010). In a study with knockout mice, Rezvani et al. (2011) identified a significant role of the hypoxia-inducible factor 1a (HIF-1a) in epidermal homeostasis, because the downregulation of HIF-1a lead to decreased expression of $\alpha 6$ integrin and $\beta 1$ integrin, diminished keratinocyte- colony-forming efficiency, and arrested cell cycle progression, which, acting together, could contribute to epidermal aging and pronounced failure in epidermal reconstruction.

Aging in hair follicles is associated with a decline of structural proteins such as certain keratins and keratin-associated proteins (KAP). While the expression of K31, K32, K36, K85 and K86 is unaffected by aging, K33A, K34 and the group of KAP4 genes produce a statistically significant decline in gene activity above 50 years of age (Giesen *et al.*, 2011). Aging additionally leads to a diminished epidermal content in specific polysaccharides, such as hyaluronic acid (HA) and

GAGs usually attached to extracellular matrix proteins to form proteoglycans (PG). Oh et al. (2011) described the age-promoted reduction in epidermal HA and heparan sulphate content, determined as an isolated GAG or composing different PGs such as perlecan and syndecan-1. According to Stern and Maibach (2008), although dermal HA is responsible for most skin HA, epidermal cells are also able to synthesize HA, mainly located in the upper SL and GL, where most of it is extracellular; BL also has HA, but it is predominantly intracellular. Proportion of total GAG synthesis devoted to HA is greater in the epidermis than in the dermis and, in senile skin, HA is still present in the dermis, whereas the HA of the epidermis seems to disappear with unknown reasons (Meyer and Stern, 1994; Stern and Maibach, 2008). An increase in the content of keratan sulphate beginning at age 50 and a decrease in chondroitin 6-sulphate after age 60 were observed in human epidermis (Willen et al., 1991). These changes may indicate declining skin physiologies, including epidermal proliferation, cell adhesion, migration and various cellular signalings (Bourguignon et al., 2006; Lundqvist et al., 2001; Parish, 2006; Tkachenko et al., 2005).

Epigenetics is also part of the age-affected mechanisms in epidermis. Proteins of the Polycomb group (PcG) are epigenetic suppressors that act by modifying histones to change the structure of chromatin and modulate gene expression and cell behavior. These proteins are found in a wide variety of cells in the progenitor, BL and suprabasal layers of the epidermis, where they regulate the keratinocyte cell-cycle progression, apoptosis, senescence, and differentiation (Eckert *et al.*, 2011). PcG protein expression, such as Bmi-1, declines in aging epidermis, which shows that a loss of PcG protein expression is associated with keratinocyte senescence both *in vivo* and in cell culture models (Cordisco *et al.*, 2010; Eckert *et al.*, 2011). The presence of the $\beta 6$ integrin subunit in epidermis helps to explain the significant delay that occurs in the wound healing of elderly people (AlDahlawi *et al.*, 2006). In addition to the decreasing numbers of structural molecules, inhibitory elements of epidermal renewal are up-regulated with age; one such element is the actin-remodeling protein Flightless I (Flil), an important mediator of wound repair by inhibiting cell proliferation and motility (Adams *et al.*,

2008). Skin immunosenescence refers to a functional immune impairment with age. In the epidermis, it is associated with decreased expression of the receptor for activated C kinase (RACK-1), defective protein kinase C (PKC) translocation, and reduced tumor necrosis factor (TNF- α) (Corsini *et al.*, 2009). Formation of advanced glycation end products (AGEs) is the result of a chemical reaction between reducing sugars and amino acids of proteins, and is related to skin aging. AGE accumulation has been extensively studied in dermal proteins, but the presence of N[£]-(Carboxymethyl) lysine was recently described in the human epidermis as affecting specifically K10 (Kawabata *et al.*, 2011).

Impact of UV light on human skin is a particular source of epidermal dysfunction throughout life. Yamada et al. (2006) found that the removal of pyrimidine dimers induced by UVB occurs more slowly in the epidermis of older individuals. Time for complete removal of dimers was 4 days in the 22- to 26-yearold group, while 14 days were needed in the 70- to 78-year-old group. DNA damage induced by generation of free radicals can be yet another pathway involved in skin photoaging. In photoaged skin, a significant depletion of antioxidant enzyme expression, including copper-zinc superoxide dismutase and catalase, was observed inside the SC and in viable epidermis (Sander et al., 2002). Transforming growth factor-beta (TGF- β) signaling in the epidermis – important for cell growth and collagen regulation – is also affected by UV-induced photoaging. Upon activation, TGF- β receptors (T β R) propagate a signal downstream to intracellular proteins termed Smads. Han et al. (2005) demonstrated that the UV-induced down-regulation of TBRII and the concerted over-expression of Smad7 in aged and photoaged epidermis may trigger the inhibition of the TGF-β-induced phosphorylation of Smad2, suggesting an active role of the epidermal compartment in the induction of age-related dermal collagen damage. S100 calcium-binding proteins are highly conserved, low-molecularweight, acidic proteins with important regulatory functions in calcium buffering, regulation of kinases and phosphatases, cell proliferation, differentiation, energy metabolism, cytoskeletal-membrane interactions, embryogenesis, cell migration, and inflammation (Donato, 2001). Lee et al. (2009b) studied changes in S100A8

expression in UV-irradiated and aged human skin *in vivo*, finding increased mRNA and protein in the sun-protected epidermis of elderly people in comparison with youth. Additionally, in the same elderly individuals, sun-exposed skin expressed more S100A8 than sun-protected areas, evincing the intrinsic involvement of S100A8 in both the aging and the photoaging processes of the epidermis.

Another example of a molecular mechanism affected in the epidermis by UV-induced aging is the regulation of alternative splicing, as in the case of the primary transcript of elastin. Elastin transcript containing exon 26A was found upregulated in keratinocytes of photoaged forearm skin compared with intrinsically aged buttock skin in the same elderly individuals, which can affect normal elastic fiber formation and contribute to the development of solar elastosis (Chen et al., 2009). Several publications point to UV-induced photoaging as an exacerbation of the signs of intrinsic aging. However, mainly at the molecular level, the result of cumulative UV exposure sometimes differs from the effect of intrinsic aging. Expression of extracellular matrix protein 1 (ECM1) in BL and upper epidermal cell layers in aged skin, for example, is significantly lower than in young skin. In contrast, and similarly to solar elastosis in the dermis, photoaging shows an increased epidermal expression of ECM1. More than impairing the regular dynamics of keratinocyte proliferation and/or differentiation, ECM1 has a key interaction with BM perlecan, and an affected ECM1 expression may impact the dermal-epidermal junction physiology (Sander et al., 2006).

Terminal differentiation of keratinocytes is marked by cell death that typically occurs in GL to originate corneocytes in the composition of the SC. There is controversy as to whether the terminal differentiation of keratinocytes is a variant of apoptosis. Both processes share activation of endonucleases and degradation of DNA. However, apoptosis differs from terminal differentiation in other respects. When comparing sun-protected skin of two groups of people with a mean age of 70 years and 23 years respectively, epidermal thinning with age was associated with a decrease in the proliferative capacity and an increase in the rate of apoptosis of keratinocytes below GL, along with a higher expression of Fas (CD95) and Fas ligand (FasL). In contrast, keratinocytes showing DNA strand breaks, which occur

at the GL as part of normal keratinocyte differentiation, do not appear related to Fas (Gilhar *et al.*, 2004).

Since cellular senescence and apoptosis occur together in aging tissues, it is important to understand their mutual relationships in aging. Wang et al. (2004) found increased senescence-associated β-galactosidase activity in aging keratinocyte cultures as well as in epidermal in vivo aging. In parallel, they observed increased levels of Fas and different components of the Fas-mediated pathway of apoptosis (such as Fas-L, FAAD adaptor and caspase-8 - all contributors to the death-inducing signaling complex, or "DISC"), higher levels of p53 (a tumor suppressor protein that can promote either apoptosis or transient growth arrest and cellular senescence), and lower levels of Bcl-2 (a mitochondrial component and crucial inhibitor of the intrinsic pathway of apoptosis) under the same conditions, both in vitro and in vivo. Moreover, when the Fas receptor was activated by antibody binding, or when the culture medium was exhausted (a possible cause of death signal induction), apoptotic cells appeared in larger numbers in senescent keratinocytes, showing that the Fas-dependent apoptotic machinery was indeed potentiated in keratinocytes at senescence. Considering the existence of distinct apoptotic pathways and of results that vary with the different experimental models, Wang et al. (2004) concluded that it was reasonable to assume that in senescent keratinocytes, the Fas-mediated pathway can be readily activated, while the p53-dependent pathway is kept in a stand-by state.

In addition to the changes affecting keratinocytes with aging, there are modifications associated with distinct epidermal cell types, such as a reduction in number of melanocytes, and a decline in the amount of Langerhans cells (which may impair the immune protection against radiation). There are also changes in the structural organization of Merkel cells (Bergman *et al.*, 2000; Ortonne, 1990; Wulf *et al.*, 2004). With aging, melanocytes become unevenly distributed in epidermis, which affects the interaction between keratinocytes and melanocytes (Ortonne, 1990). The number of functional melanocytes in nonexposed human skin decreases with age, at a rate of 8-20% each decade. However, in UV-irradiated skin there are approximately twice as many melanocytes as in unexposed areas,

but there is still a comparable decrease in melanocytes with age (Costin and Hearing, 2007). Secretion of melanocyte-stimulating cytokines was impaired in old donors (Okazaki et al., 2005). mRNA expression and activity of nicotinamide adenine dinucleotide (NADH) dehydrogenase decreases in late passage cultures of keratinocytes, suggesting reduction in enzyme production with epidermal aging (Nakama et al., 2012). Furthermore, inhibition of NADH dehydrogenase induces production of reactive oxygen species (ROS) in mammalian tissue (Paradies et al., 2004). As positive feedback, increased levels of ROS induce the production of IL-1a and endothelin 1 (EDN1), upregulation of tyrosinase expression, and acceleration of skin melanogenesis (Hughes et al., 1996; Karg et al., 1993; Nakama et al., 2012). Consequently, age-related decrease in NADH dehydrogenase might be directly involved in the regulation of keratinocytemelanocyte signaling, and lead to increased skin pigmentation. Mouse models also indicate age-dependent reduction in Langerhans cell frequency without affecting their survival and proliferation in epidermis, suggesting either a deficiency in bone marrow-derived Langerhans cell progenitors, or a less responsive profile to signals known to be required for the recruitment of these progenitors into skin. Functionally, the capacity of aged Langerhans cells to induce T cell priming is impaired. Moreover, expression of microRNAs (miRNAs) in aged epidermal Langerhans cells shows an altered profile in comparison with that of a young epidermis, a condition that is especially noteworthy in miRNAs related to the downregulation of TGF-B signaling pathway, which affects the development of Langerhans cells (Xu *et al.*, 2012). TNF-α-induced migration of Langerhans cells appears reduced in elderly (Bhushan et al., 2002). However, another study concluded that phenotype and function of monocyte-derived Langerhans cells are not altered by aging, and that changes in the epidermal environment are likely to be more important (Ogden et al., 2011). Notwithstanding a few differing opinions, in the photoaging of human skin, the numbers of Langerhans cells are inversely proportional to photodamage severity: cells are reduced by up to 50% in UVexposed skin areas in comparison with UV-protected skin areas (Grewe, 2001). Regarding the effect of aging on the epidermal sensorial system, a decrease in the

target neurotrophin (NT) expression has been demonstrated, particularly in NT3 and NT4, which results in a site-specific loss of sensory terminals with a reduction in the number of Merkel cell-neurite complexes (Bergman *et al.*, 2000).

Unstopping the plughole: biological and physicochemical properties and SC desquamation

The third step of the bath model, desquamation (Figure 1), emphasizes SC structure and organization. Basically, SC is composed of two compartments: intact, lipid-depleted and protein-enriched corneocytes, which represent the "bricks" embedded in a continuous, lipid-enriched (mainly ceramides, cholesterol and free fatty acids) extracellular matrix that is organized into functional membrane bilayers representing the "mortar" (Michaels *et al.*, 1975). The construction of competent epidermal lipid bilayers takes place according to the following sequence: lipid synthesis, secretion of lamellar body lipids at the GL-SC interface, and extracellular processing of secreted polar lipid precursors into a hydrophobic mixture that forms functionally competent lamellar membranes (Choi *et al.*, 2007). In fact, corneocytes in the SC are dead cells, but this does not make it an inert layer. On the contrary: SC is metabolically active and interactive with the underlying nucleated cell layers of the epidermis (Elias and Ghadially, 2002). Changes that the SC suffers with aging have a great impact on the epidermal permeability barrier, damaging the basic composition of the "brick and mortar" model (Figure 5).

Xerosis is an uncomfortable manifestation of aged skin, which may result from a decrease in lipid synthesis (Akimoto *et al.*, 1993). Schmuth *et al.* (2005) showed differences in production of fatty acid transport proteins between embryonic and adult epidermal tissues, indicating that a dynamic regulation of these constituents is active throughout the development stages of an individual. Ghadially *et al.* (1995) found a reduction in the delivery of secreted lipids to the SC, resulting in less extracellular lamellar bilayers. There is an overall reduction in aged SC lipids that totals about one third less lipid weight percentage than in young SC, suggesting that aged epidermis possibly has a more porous extracellular matrix

than the young one (Elias and Ghadially, 2002). In addition, several molecular pathways involved in SC lipid metabolism are down-regulated at the level of gene expression in the aging skin and probably contribute to the decreased capacity of aged skin to maintain and repair the epidermal barrier (Jarrold *et al.*, 2009). Decreased levels of IL-1 α with chronologic aging must be associated with a decreased production of epidermal lipids (Ye *et al.*, 1999). According to Ghadially *et al.* (1996), cholesterol seems the most age-affected class of lipids in the SC, which shows a reduced deposition of cholesterol molecules and a decreased activity of its rate-limiting enzyme, 3-hydroxy-3-methylglutaryl-coenzyme A reductase. Several studies show that different classes of SC lipids are differently affected by aging.

Figure 5. Stratum corneum (SC) organization. (1) "Brick and mortar model" proposed by Michaels *et al.* (1975) highlights the main components of SC structure: the "bricks" are lipid-depleted and protein-enriched dead corneocytes embedded in the "mortar", which is composed of a continuous, lipid-enriched (mostly by ceramides, cholesterol and free fatty acids) extracellular matrix organized into functional membrane bilayers. Extracellular pH is neutral up to the transition between granular layer (GL) and SC. Then it turns more acidic and reaches approximately 4.5 up to the skin surface,

where there is a hydrolipidic or acid mantle composed of a mixture of sebum, sweat, corneocyte debris and constituents of natural moisturizing factors. (2) Corneodesmosomes – structures derived from desmosomes – are responsible for securing the cohesion of intercorneocytes, and are present at the cell edges on the skin surface. Corneodesmosomes are incorporated into the cell membrane or cornified envelope and are composed of several cytoplasmic (plakoglobins, desmoplakins and plakophilins), transmembrane (desmogleins and desmocollins) and extracellular proteins (corneodesmosin). Corneodesmosomes are progressively degraded by several serine, cysteine and aspartic enzymes, including kallikrein-related peptidases and cathepsins. This facilitates the desquamation process which is characterized by the release of corneocytes from the skin surface by friction forces.

Epidermal ceramides are obtained by hydrolysis of sphingomyelin or else by means of a synthesis from sphingosin and fatty acids, and are degraded by ceramidase. Sphingomyelinase activity declines with age: 80-year-old individuals have 25% of the activity found in 20-year-olds (Yamamura and Tezuka, 1990). Denda et al. (1993) demonstrated age- and sex-dependent change in SC sphingolipids, by evaluating ceramides 1-6. No differences were found in men, while women showed significant modifications: from prepubertal age to adulthood, ceramides 1 and 2 increased while ceramides 3 and 6 decreased; after reaching maturity, ceramide 2 decreased and ceramide 3 increased with age. These results suggest a significant influence of female hormones on SC sphingolipid composition. De Paepe et al. (2004) found sex-related differences at the level of total ceramide concentration: there were higher ceramide concentrations in men as compared with age-matched females. Effect of aging was significant only for a decrease in cholesterol sulfate and cholesterol concentrations in the abdominal skin. However, evaluations of the total amounts of lipids showed no changes due to sex or aging, which calls into question the high intervariability of the studies of lipids in the human SC, because of the different origins of the skin samples and variety of extraction methods currently in use. Jensen et al. (2005) used a mice model to identify the age-related reduction in acid sphingomyelinase (A-SMase) and ceramide synthase activities, but the changes were observed only in the inner layers of epidermis, not the SC.

Regarding SC free fatty acid composition, Kim et al. (2010a; 2010b) studied the effect of aging in photoprotected and photoexposed areas of the skin. Levels of palmitic acid, stearic acid, linoleic acid and 11,14,17-eicosatrienoic acid (ETA) decreased in aged skin by 15%, 31%, 7%, and 56%, respectively, in comparison with levels of the same acids in young skin. In contrast, palmitoleic acid and oleic acid levels increased in aged skin by 67% and 22%, respectively. Levels of palmitic acid and stearic acid in photoaged forearm epidermis decreased by 11% and 23%, respectively, compared with levels of these acids in the buttock skin of the same elderly individuals. Conversely, amounts of linoleic acid and ETA in photoaged forearm epidermis increased by 19% and 69%, respectively. The authors emphasized the results for ETA, an omega-3 polyunsaturated acid, which increased significantly in photoaged human epidermis in vivo, but decreased significantly in intrinsically aged epidermis. They also demonstrated that ETA inhibited MMP-1 expression after UV-irradiation, which may suggest the existence of a photoprotective effect for human skin. In general, Kim et al. (2010a; 2010b) concluded that the amounts of free fatty acids and triglycerides decreased significantly in the epidermis of photoaged human SC. Moreover, the expression of genes related to lipid synthesis, including acetyl-CoA carboxylase (ACC), fatty acid synthase (FAS), stearoyl-CoA desaturase (SCD), sterol regulatory element binding proteins (SREBPs), and peroxisome proliferation-activated receptors (PPARy) decreased markedly with photoaging.

Although several studies focus on differences in the composition of lipids and on the regulatory mechanisms related to lipid synthesis, secretion and processing of lipids are crucial steps in construction of an efficient epidermal barrier. Secretion is regulated by changes in extracellular calcium and potassium concentrations (Mauro *et al.*, 1998a and b; Menon *et al.*, 1985). Association of calcium with lamellar body disc membranes and contents suggests that it may contribute to lamellar body secretion as well as to the formation of intercorneocyte membrane bilayers (Menon *et al.*, 1985). In addition, selective obliteration of the epidermal calcium gradient by means of sonophoresis enhanced lamellar body secretion (Menon *et al.*, 1994). As previously mentioned, aging hinders the

formation of calcium gradients in epidermis (Denda et al. 2003). It can therefore be said that age-induced changes in the distribution of calcium in the epidermis may have an impact on the SC formation in elderly individuals. While lipid secretion is strongly influenced by ions, lipid processing is controlled by the pH of the extracellular spaces and requires two acidity-dependent lipid hydrolases: βglucocerebrosidase (BCG) and A-SMase (Hachem et al., 2005). SC normally has a low pH value, which favors the enzymatic activity necessary for its formation. However, changes in pH values may cause modifications in the enzymatic dynamics of the SC; again, aging is a relevant factor in the control of the pH on the skin surface. Choi et al. (2007) demonstrated that SC acidification is already weakened in moderately aged human and murine skin, showing that pH value rises progressively in aged humans beginning at about age 50. Prolonged SC neutralization causes profound abnormalities in SC function, due to the activity of pH-induced high serine proteases, which, in turn, degrade lipid processing enzymes, such as BCG and aSM'ase (Hachem et al., 2005). Investigating the molecular regulation of pH changes in the SC, Choi et al. (2007) found a diminished Na⁺/H⁺ antiporter (NHE1) expression that lead to increased pH values in the SC and, consequently, to defective processing of lipids and delayed maturation of lamellar membranes.

Nevertheless, divergences should be noted in results regarding continuous pH increase with aging. Luebberding *et al.* (2013) evaluated 150 women aged 18 to 80 years and found decreased surface pH associated with a continuous decline in sebum production with age. Interestingly, pH decrease was not observed in moderately aged, 50-60 year-old women, who showed slightly increased pH values. In a large Chinese panel consisting of 713 subjects, skin surface forehead pH of males and females over the age of 70 was higher than in younger groups (Man *et al.*, 2009). These differences could, of course, be attributed to different experimental designs and applied techniques, but they are in agreement with the finding of impaired acidification in moderately aged epidermis. According to Choi *et al.* (2007), advanced aging is likely to reveal a combination of abnormalities in the synthesis and processing of lipids; however, at least in moderately aged epidermis,

barrier dysfunction due to an impaired acidification of the SC leads, not to an abnormal synthesis, but to a diminished processing of lipids.

Antimicrobial protection depends on the maintenance of an acid pH in the SC to create an ecological milieu that is simultaneously hostile to microbial pathogens and favorable to the growth of the normal flora. Rodriguez-Martin et al. (2011) evaluated antimicrobial peptides in a mouse model for aging and found reduced levels of cathelicidin antimicrobial peptide (CAMP) and increased levels of β -defensin 3 (BD3) and of the neuroendocrine peptide catestatin (Cst). Whether further abnormalities in antimicrobial defense mechanisms occur in moderately aged and/or more-advanced aged and/or photoaged epidermis is not known. However, taken together, these findings suggest that antimicrobial protective function of SC might become impaired relatively early in older people. Mixture of sebum and small amounts of lipids, produced by keratinizing epidermal cells (mainly corneocytes), forms the skin surface lipids (SSL) that mantle human epidermis, and thus constitutes a protection of the body against exogenous oxidative insults (Passi et al., 2002). Total SSL vary according to sex and age: they are higher in males than in females, peak at maturity and diminish with age because of a reduction in the activity of sebaceous glands (Cotterill et al., 1972). Different fatty acids of triglycerides seem to follow the activity of the sebaceous glands: they are higher at maturity than in childhood and advancing age; while squalene, vitamin E and Coenzyme Q₁₀ increase from childhood to maturity to decrease again significantly in old age (Passi et al., 2002). These results suggest important changes at the top of SC with aging, which may be indicators of lowered protection against exogenous oxidative insults, particularly from harmful UV rays. Mixture of SSL, from sebum and corneocyte debris, with water, and from sweat and substances derived from protein degradation such as NMFs, compose the hydrolipidic or acid mantle (Shetage et al., 2013).

Regarding protein component of SC as part of its "bricks", Takahashi and Tezuka (2004) observed reduction in protein level of filaggrin in older epidermis, while the mRNA level was not affected by age, and formation of natural moisturizing factors (NMF) derived from enzymatic degradation of filaggrin

increased in elderly individuals. Consequently, the reduction in the protein level of filaggrin might be caused not only by changes affecting gene expression, but also by intensified proteolytic activity, which may degrade epidermal filaggrin before it can form large molecules (Takahashi and Tezuka, 2004). It is also essential to look at the organization of corneodesmosomes - the modified desmosomes that are present in corneocytes to keep them attached to each other. Corneodesmossomes are major determinants of SC cohesiveness; they are lodged in the edges of the cells on the surface of the skin, incorporated in the cell membrane or cornified envelope, and composed of several cytoplasmic (plakoglobins, desmoplakins and plakophilins), transmembrane (desmogleins and desmocollins) and extracellular proteins (corneodesmosins) (Chapman *et al.*, 1991; Ishida-Yamamoto *et al.*, 2011; Rawlings, 2003). During corneocyte maturation, corneodesmosin is progressively proteolyzed (Ishida-Yamamoto et al., 2011). Both exogenous and endogenous proteases are involved in the cleavage of the corneodesmosome junctions. Among endogenous proteases, there are several serine, cysteine and aspartic enzymes, including kallikrein-related peptidases (KLK) and cathepsins, both produced by keratinocytes (Ishida-Yamamoto et al., 2011; Rawlings, 2003). The pH-induced high serine protease activity caused by impaired acidification of the SC with aging also degrades corneodesmosome proteins, such as desmoglein 1 (Hachem et al., 2005). This complements the finding that corneocyte detachment becomes more prevalent with age, and helps to explain the prevalence of xerosis and pruritus in the elderly (Chu and Kollias, 2011; White-Chu and Reddy, 2011).

Usually, changes that are seen in chronologically aged skin are further aggravated (by about 20%) in human skin areas with superimposed photoaging (Elias and Ghadially, 2002; Reenstra *et al.*, 1996). Shekar *et al.* (2005) applied microtopography to show that deterioration of fine reticular patterning of the SC, also referred to as skin pattern on the Beagley-Gibson scale, occurs over time. In an elegant study, they estimated the extent to which changes are due to genetic or environmental influences by analyzing nuclear twin families. Variation in skin pattern was due to genetic influences in the proportion of 86% at age 12, 75% at age 14, 72% at age 16, and 62% in an adult sample aged between 32 and 86

years. While the genetic influence decreased with aging, environmental factors appeared to have a growing and cumulative impact throughout the lifetime. Analyses of the adult group showed that extrinsic components were related to a more extensive deterioration in the skin pattern but, surprisingly, caused very little variation in the adult skin pattern (less than 2%), which was explained by the inability to tan and prolonged outdoor work. The results corroborated previous data, and also concluded that the variation in stratum corneum patterning was indicative of intrinsic skin aging rather than photoaging (Seddon *et al.*, 1992). Subsequently, Shekar *et al.* (2006) conducted the first genome-wide linkage scan study of epidermal reticular patterning with adolescent twins and siblings, and found a suggestive linkage at chromosomal markers such as 12p13.31 and 4q23. Identified regions in chromosomes probably correspond to genetic factors associated with the structure or regulation of the epidermis, like MMP and protease inhibitor α -2-macroglobulin, as well as the subunit 1 of NF- κ B involved in regulating keratinocyte differentiation and proliferation.

Concluding remarks and future perspectives

Increasing number of studies related to the epidermis is a clear indication of its importance as a dynamic structure in the control of skin and organism homeostasis. Recent cell biology studies provide consistent evidence to propose a working model for renewal of the epidermis, based mainly on the emerging researches on epidermal proliferative cells, which allow discussing the new significant findings about epidermal development and aging. An innovative in silico study was developed to model long-term colony dynamics in the epidermis, as a complement to experimental studies (Li *et al.*, 2013). Different models were challenged using the in silico approach, and hypothesis of populational asymmetry with stem cells (Mascré *et al.*, 2012) provided the best mechanism for sustained tissue regeneration and homeostasis.

Cell signaling studies also indicate great opportunities to discover the major pathways related to the physiology and aging of the epidermis. This has been

significantly accelerated with the application of new "omics" techniques based on global analyses and associated with the birth of bioinformatics technologies. The term "skinomics", for example, was applied to define the transcriptional profiling in dermatology and skin biology (Blumenberg, 2012). A number of studies have been conducted to understand global mRNA or protein expression of human epidermis, which harbors a wealth of information about the genes involved in skin function and genetic skin disorders (Jansen and Schalkwijk, 2003). An extensive study using DNA microarrays quantified and described considerable differences in the transcriptional profiling of epidermal keratinocytes, by comparing the gene expression in skin, cultured keratinocytes, and reconstituted epidermis (Gazel et al., 2003). An Investigation of the transcriptome of accelerated and replicatively senescent keratinocytes revealed links to differentiation, interferon signaling, and Notch related pathways (Perera et al., 2006). Despite their important contributions to the understanding of epidermal physiology, the above-cited works were not directly intended to explain the effects of aging on epidermis. Several conclusions on epidermal aging could of course be drawn from analyses of senescent keratinocytes, but important considerations must be taken into account when comparing cell biology mechanisms of in vitro senescence with those of in vivo aging (Hwang et al., 2009). Other studies used in vivo human biopsy samples for global molecular analyses of skin aging; these studies, however, fail to supply specific information about how epidermis ages, since skin biopsies also contain (confounding) dermal material (Laimer et al., 2010; Lener et al., 2006). Gromov et al. (2003) conducted the only work that targeted analysis of in vivo epidermal aging by adopting an "omics" approach. By isolating an enriched epidermis portion of skin biopsies from young and old individuals, they analyzed protein profiling of the human epidermis from elderly persons and substantiated the argument that aging is associated with increased severe oxidative stress and alterations in the signaling of apoptosis. Therefore, platforms based on global analyses at different molecular levels represents a promising alternative to define new pathways inscribed in the aging of the epidermis. In addition, mechanisms other than the regulation of epidermal process, such as differentiation and cornification, have begun to be

understood and interconnected with functional and/or clinical signs in the elderly. Specifically for this purpose, study of premature aging and associated comorbidities, such as the Hutchinson-Gilford progeria syndrome and the Werner syndrome, offers an alternative for understanding key molecular components in the aging process (Capell *et al.*, 2009; Coppedè, 2013; Navarro *et al.*, 2006).

Effects of physical, chemical and biological agents on the aging of the epidermis might provide a powerful way to find new therapeutic opportunities that are more effective and directed to specific pathways or molecular targets. Epidermal keratinocytes are complex cells that create a unique three-dimensional structure, which differentiates through a multistage process and responds to environmental and extracellular stimuli from nearby cells (Gazel et al., 2003). In addition, epidermal keratinocytes have been the target of many studies because they respond to a rich variety of inflammatory and immunomodulating cytokines, hormones, vitamins, ultraviolet (UV) light, toxins, and physical injury (Blumenberg, 2006). Modulation of gene expression, and possibly of many other molecular levels, is a reality that can be applied to fight aging effects on skin tissue (Talbourdet et al. 2007). Expression of molecules related to the ability of skin to sense the external environment was identified out of neuronal cells, such as TRV channels in the cell membrane of keratinocytes, suggesting new routes to sensitive properties of epidermis (Denda et al., 2001b). Moreover, a thorough understanding of molecular skin aging may, in a not-too-distant future, permit the efficient application of pharmacogenomics using individualized drug therapies based on genomic biomarker identification, which would avoid potential side effects while maximizing therapeutic response (Greenfield and Maibach, 2012; Rizzo and Maibach, 2012). In this sense, increasing knowledge about epidermal aging, which has a direct influence on response to topic treatments, should result in considerable gains in the field of personalized medicine and drug delivery optimization.

Dynamics of aged skin barrier shows particularities to such an extent that drug pharmacokinetics and pharmacodynamics may be altered in the elderly (Flammiger and Maibach, 2006). Maibach's group has extensively studied

percutaneous drug absorption, including changes promoted by an altered barrier function in aged epidermis (Harvell and Maibach, 1994; Konda *et al.*, 2012a and 2012b; Roskos *et al.*, 1986, 1989 and 1990). It is a common misconception, for example, that older skin has a diminished barrier capacity, and that percutaneous absorption is therefore greater (Oriba *et al.*, 1996). A better understanding of the changes affecting epidermal barrier with age is fundamental for the development of more efficient treatments and reduction of dermatotoxicological effects in elderly individuals (Ngo and Maibach, 2010).

Challenges that face elucidation of complex epidermal interactions and even the understanding of functional signaling in the epidermis with aging are far from complete. Several possibilities emerge for future perspectives, including development of functional assays to identify key protein players in epidermal stem cell proliferation and differentiation; of cell sorting and gene expression studies to shed light on age-related changes in homeostasis for each epidermal cell type; and perhaps of an investigation of functional interplay between different cells in epidermis. Epidermal bath model should be continuously revisited and refilled with recent scientific data, not only as a framework for understanding mechanisms involved in skin aging, but also as a helpful tool for the development of improved therapies to improve, reinforce and/or restore the function of healthy skin.

This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

1) Epidermis and the evolution toward a global understanding of skin aging.

2) Molecular, cell-related, and morphological changes in aged epidermis.

3) Active ingredients in the recovery of specific age-affected epidermal functions.

Abstract

The decisive role of the epidermis in maintaining body homeostasis prompted studies to evaluate the changes in epidermal structure and functionality over the lifetime. This development, along with the identification of molecular mechanisms of epidermal signaling, maintenance, and differentiation, points to a need for new therapeutic alternatives to treat and prevent skin aging. In addition to recovering age- and sun-compromised functions, proper treatment of the epidermis has important aesthetic implications. This study reviews active ingredients capable of counteracting symptoms of epidermal aging, organized according to the regulation of specific age-affected epidermal functions: 1) several compounds, other than retinoids and derivatives, act on the proliferation and differentiation of keratinocytes, supporting the protective barrier against mechanical and chemical insults; 2) natural lipidic compounds, as well as glycerol and urea, are described as agents for maintaining water-ion balance; 3) regulation of immunological pathogen defense can be reinforced by natural extracts and compounds, such as resveratrol; and 4) antioxidant exogenous sources enriched with flavonoids and vitamin C, for example, improve solar radiation protection and epidermal antioxidant activity. The main objective is to provide a functional classification of active ingredients as regulatory elements of epidermal homeostasis, with potential cosmetic and/or dermatological applications.

<text>

1. Introduction

Epidermis, the most exposed skin part, directly contacts the external environment. It is assembled by multiple superposed cell layers that form an effective protection barrier (Baroni et al., 2012; Madison, 2003). As a complex system, which also captures environmental stimuli, epidermis is composed of several cell types such as keratinocytes, melanocytes, Langerhans cells, and Merkel cells (Boulais and Misery, 2008). Keratinocytes are the most abundant cell type constituting 80-95% of epidermal cells (Brohem et al., 2011; Ulmann et al., 2007).

Due to constant desquamation, epidermis needs continuous renewal, which begins with multiplication of proliferative cells in the innermost layer, generating keratinocytes that undergo differentiation as they are driven outwards with cell divisions (Fuchs and Raghavan, 2002; Milstone, 2004). Keratinocyte differentiation is marked by molecular, structural, and functional changes, resulting in a stratified epidermis in which the different strata, arranged from the inner to the outer surface, constitute the basal layer (BL), spinous layer (SL), granular layer (GL), and stratum corneum (SC), respectively (Fuchs and Raghavan, 2002; Simpson et al., 2011). The palms and soles possess an additional layer – stratum lucidum (SL) – between GL and SC (Brohem et al., 2011). In SC, keratinocytes reach their highest level of differentiation and are then known as corneocytes – dead, enucleated, and morphologically flat cells composed of protein and lipid blocks bonded to one another and immersed in a lipid matrix (Eckhart et al., 2013).

More than just a barrier for mechanical protection, epidermis is a metabolically active tissue in constant dynamic balance and periodically undergoes complete renewal cycles (Fuchs and Raghavan, 2002). The working of the epidermis seems paradoxical, since it is highly stable in protecting the organism from external aggression and, at the same time, allows its cell components the required flexibility to ensure tissue renewal and capability of response to different stimuli (Simpson et al., 2011). This ability makes the epidermis a decisive component for maintaining body homeostasis. Over the years, however, epidermal primary functions may gradually falter (Elias and Ghadially, 2002). Physiological wear from skin aging is a consequence of damage that accumulates throughout the organism's life and is caused both by intrinsic factors (physiological components and genetic predisposition) and extrinsic factors (external insults, particularly from solar radiation) (EI-Domyati et al., 2002; Farage et al., 2008a). Molecular, cell-related, and morphological changes in aged epidermis not only compromise its protective role, but also contribute to the appearance of skin symptoms, including excessive dryness and pruritus (White-Chu and Reddy, 2011), as well as increased predisposition to formation or deepening wrinkles (Kuwazuru et al., 2012), dyspigmentation (Longo et al., 2013), fragility and difficulty to heal injuries (Bourguignon et al., 2013; Calleja-Agius et al., 2007), alteration in skin permeability to drugs (Bourguignon et al., 2013), impaired ability to sense and respond to mechanical stimuli (Wu et al., 2011), skin irritation (Bourguignon et al., 2013), and tumor incidence (Farage et al., 2008b; Wolf et al., 2013) (Figure 1).

Skin aging involves systemic changes as well as changes in the entire skin (Waller and Maibach, 2006 and 2005; for details, refer to Farage et al., 2010). Although most investigations still concern dermis, mainly because of its abundant content in extracellular matrix (ECM), recent studies have targeted epidermal aging and possible therapeutic options. In addition to their health-related implications, epidermal alterations can lead to changes in appearance or image that may have a high aesthetic and psychosocial impact (Jiang and DeLaCruz, 2011). Moreover, search for therapeutic alternatives that include the epidermis is an additional step toward an integrating approach to skin aging treatment and prevention.

This manuscript overviews active ingredients identified for the treatment of skin aging. They are grouped according to their specific activity in the recovery of epidermal functions and include the following major topics: 1) protective barrier against mechanical and chemical insults (Lulevich et al., 2010; Kirschner et al., 2013), 2) maintenance of water-ion balance in the organism (Kirschner et al., 2013; Proksch et al., 2008), 3) immunological defense and toxin elimination (Baroni et al., 2012; Geusau et al., 2001; Polak et al., 2014), and 4) solar radiation protection and antioxidant activity (Shindo et al., 1994; Yamaguchi et al., 2006). Overall, current active ingredients were searched for potential cosmetic and/or dermatological applications, according to their biological and biophysical effects on the regulation of age-impaired epidermal homeostasis.

2. Protective Barrier against Mechanical and Chemical Insults

Protection against mechanical and chemical insults depends directly on the structural epidermal integrity - a stratified arrangement of superposed cell layers with keratinocytes bonded by means of intercellular junctions and extracellular matrix components (Ishida-Yamamoto et al., 2011; Kirschner et al., 2013; Lulevich et al., 2010). A primary factor for preserving skin barrier is its capability for cell renewal, affected by the keratinocyte proliferation rate and differentiation (Cangkrama et al., 2013). Distinct mechanical properties of keratinocytes, including their high deformation resistance, which may be up to seventy times that of other cells in the organism, contribute significantly to their protective action (Lulevich et al., 2010). This resistance is largely due to the keratin cytoskeleton acquired along the epidermal cell differentiation process: complete keratin deletion causes significant biomechanical deficiencies in keratinocytes (Bragulla and Homberger, 2009; Kim et al., 2012b; Ramms et al., 2013). Chemical composition of the epidermis, which also plays a part in the protection against mechanical and chemical insults, will be discussed more detailedly in Section 3 due to its high relevance to maintenance of the water-ion balance in the organism.

Reduction in epidermal thickness – one of the morphological characteristics of ageaffected skin – results from lower cell renewal rates due both to intrinsic and extrinsic factors (Crisan et al., 2012; Shlivko et al., 2013; Tsugita et al., 2013; Waaijer et al., 2012). The number of layers containing viable cells diminishes with

epidermal aging, and keratinocyte proliferation and differentiation are significantly impaired in elderly persons' epidermis (Bourguignon et al., 2013; Levakov et al., 2012; Lock-Andersen et al., 1997). Senescent cell build-up may also play a role in the diminishing regenerative capacity of aged biological tissues, including epidermis (Cordisco et al., 2010). In addition, changes that occur in the cells and extracellular matrix suggest a more porous and less effective structural organization of the aged epidermis as regards its barrier function against external chemical agents (Elias and Ghadially, 2002).

Active ingredients that regulate the protection against mechanical and chemical insults should be capable of restoring cell renewal in aged epidermis and thus ensure integrity in the skin barrier. In addition to the possibilities here identified, physical treatments such as photodynamic (Orringer et al., 2008), high-energy pulsed CO₂ laser (Ratner et al., 1998; Stuzin et al., 1997), and fractional CO₂ laser (Sasaki et al., 2009) therapies are suggested as options for epithelium renewal and keratinocyte proliferation incitement action. **Table 1** lists ingredients capable of supporting the protective epidermal barrier against mechanical and chemical insults, including literature-enshrined elements, such as retinoids and their derivatives (for recent review, see Babamiri and Nassab, 2010), as well as alpha-hydroxy acids (AHAs) (for recent review, see Babilas et al., 2012) and several other compounds.

Regarding retinoic acids, a large set of data has already been published describing their effect on the proliferation and differentiation of keratinocytes, that directly affects wrinkles appearance and formation (Bellemère et al., 2009; Skazik et al., 2013). Retinoids are also used for photoaged skin treatment, since they reduce skin hyperpigmentation (Gold et al., 2013; Kircik, 2012) and inhibit metalloproteinases expression (Jurzak et al., 2008). Besides these well-known properties, retinoids have recently been described in the regeneration of hair follicles by promoting functional differentiation of dermal papilla cells (Aoi et al., 2012) and, in association with minoxidil, they prevent apoptosis of dermal papilla cells (Kwon et al., 2007). Side effects upon use of retinoic acids are related to their potential to cause skin irritation. Another potential inconvenience of retinoic acids involves its instability in topical formulations. Interestingly, these problems have led to the development of retinoid derivatives and similar compounds with superior properties (Kim et al., 2011 and 2010). AHAs, such as glycolic and lactic acid, are also used to treat photodamaged skin (Rendl et al., 2001) and to stimulate epidermal renewal, with clinical improvements in skin thickness, firmness, and softness, as well as in the appearance of fine lines and wrinkles (Bhattacharyya et al., 2009; Yamamoto et al., 2006). They reduce the calcium ion concentration in the epidermis and remove calcium ions by chelation, disrupting cell adhesions and resulting in desquamation (Wang, 1999).

3. Maintenance of Water-Ion Balance in the Organism

Epidermis plays a fundamental part in sustaining internal homeostasis in the organism by controlling the exchange of substances, especially water and ions, with the external environment (Tzaphlidou, 2004). Hydration also determines the general aspect of the skin; since the entire cell metabolism can be affected by the amount of water it contains (Jiang and DeLaCruz, 2011). To preserve this functionality, in addition to the cell structure discussed previously, epidermis shows an arrangement of biochemical components with selective properties. In SC, for example, the extracellular matrix contains 75-80% of proteins, 5-15% of lipids, and 5-10% of other constituents (Förster et al., 2009). Lipid fraction consists primarily of ceramides, fatty acids, cholesterol, esters, triglycerides, and phospholipids (Lampe et al., 1983). Part of the highly insoluble and resistant SC proteins, such as loricrin and involucrin, corresponds to corneocyte envelope (Hansen et al., 2009; Kalinin et al., 2001; Nishifuji and Yoon, 2013). Moreover, to preserve water and soluble ions, epidermis has differentiated molecular mechanisms, such as natural moisturizing factors (NMFs) derived from profilaggrin proteolysis, which form an intensely hygroscopic mixture composed of peptides, amino acids and their derivatives (such as urocanic acid (UCA) and 2-pyrrolidone-5-carboxylic acid (PCA)), minerals, urea, and sugars (Bouwstra et al., 2008; Kezic et al., 2009; Zhang et al., 2006). Aquaporins (AQPs) are channels that run along epidermal cell membranes to carry water and small molecules of solute, which are essential for maintaining water-ion balance of the cell. Of the thirteen AQP types described in humans, the most extensively studied AQP in the skin is AQP3, found chiefly in epidermal basal cells (Hara and Verkman, 2003; Takata et al., 2004). Recently, AQP10 has also been

identified in human epidermis, specifically in SC corneocytes (Boury-Jamot et al., 2006; Jungersted et al., 2013). AQP3 and AQP10 belong to the same aquaglyceroporin subclass; they are known to transport water and glycerol – the latter being an important agent for the hydration, resilience and repair of the skin barrier (Fluhr et al., 2008).

Aging significantly affects the epidermal function of controlling the balance of water and ions in the body. Lipid synthesis diminishes with age, as does the secretion of lamellar bodies in SC which generates an extracellular matrix that is more porous and less efficient in controlling the water-ion balance in the organism (Elias and Ghadially, 2002; Ghadially et al., 1995). Many molecular pathways related to SC lipid metabolism are downregulated in aged skin; and cholesterol seems to be the most affected lipid class (Ghadially et al., 1996; Jarrold et al., 2009). In specific cases, such as solar lentigo (an aging mark in photoexposed skin areas), a reduction occurs in the expression of cornified envelope-related genes, such as filaggrin and involucrin (Aoki et al., 2007). Free amino acid content of NMF's seems lower in the SC of senile epidermis (Jacobson et al., 1990). Expression AQP3 levels diminish with the aging of human epidermis and also in isolated keratinocytes, probably related to the development of xerosis (excessive skin dryness commonly seen in the elderly) (Li et al., 2010).

As therapeutic alternatives for recovering the epidermal function that preserves the water-ion balance in the organism, active ingredients should promote

replenishment or stimulate the endogenous synthesis of affected biochemical components. **Table 2** lists the most frequently used components for this specific function, such as waxes, natural oils and derivatives, whose lipid composition either mimics that of SC elements or acts complementarily on skin hydration (for critical considerations, see Draelos, 2013), as well as compounds that stimulate endogenous synthesis of epidermal biomolecules, including glycerol and urea (for details, refer to Lodén and Maibach, 1999).

Among the compounds widely used for maintenance of water-ion balance are glycerol and urea, as they are able to sustain the physical properties of hydrated lipid systems under dry conditions (Björklund et al., 2013). Comparison of the effects of these compounds on water distribution in the SC of human skin equivalents suggested distinct patterns of action. While water domains were mainly located in the intercellular regions under urea treatment, water was observed both in intercellular regions and in corneocytes following glycerol treatment (Bouwstra et al., 2012). A fine-tuned regulation of AQPs expression is also involved in the maintenance of water and solute balance in the skin (Hara and Verkman 2003). It has been shown that mice lacking AQP3 have impaired SC hydration and skin elasticity and a threefold reduction in their glycerol content. However, all these effects were compensated with orally administered glycerol, restoring the epidermal barrier function (Hara and Verkman 2003). Peptides and standardized plant extracts have already been reported to increase expression of the AQP3

gene in cultures of human keratinocytes, but such studies usually lack consistent clinical trials to confirm their function *in vivo*.

4. Immunological Defense and Toxin Elimination

Regulation of epidermal defense mechanisms is crucial for local and systemic homeostasis of the organism. Existence of a complex, unified skin defense system, described as a cutaneous neuroimmunoendocrinological system, has been suggested (Brazzini et al., 2003; Misery, 2000; O'Sullivan et al., 1998). Epidermal cells - including keratinocytes, melanocytes, and Langerhans cells - can produce, either constitutionally or by activation, an arsenal of cytokines (Table 3) and thus reinforce the action of epidermis as a tissue that is immunocompetent and active in creating an immunological barrier (Corsini and Galli, 2000; Kupper and Fuhlbrigge, 2004; Williams and Kupper, 1996). Langerhans cells act as sentries for epidermis and ensure the activation of adaptive immune response by presenting antigens to T-cells (Cumberbatch et al., 2003). Epidermis also acts as an adjuvant in the potentiation of inflammatory pathways and in the preparation of more efficient systemic immune responses with improved B- and T-cell activation (Gutowska-Owsiak and Ogg, 2012; Liu et al., 2010). In addition, the epidermal surface exhibits particular properties for a defense strategy against potential pathogens. The strategy includes maintenance of commensal microorganisms capable of producing competitor-inhibiting substances, secretion of antimicrobial peptides named defensins, and maintenance of acid pH levels to hinder the installation and

growth of certain microorganisms (Harder et al., 2013; Namjoshi et al., 2008; Niyonsaba et al., 2009). Although scantily reported to date, there are indications that epidermal desquamation helps to eliminate toxins such as 2,3,7,8tetrachlorodibenzo-p-dioxin (TCDD) (Geusau et al., 2001).

As the skin ages, agents that stimulate the epidermal immune defense system undergo significant changes: total number of Langerhans cells diminishes, as does their functional capability (Ogden et al., 2011; Xu et al., 2012); secretion level of IL-1 is reduced and affects mitotic capacity and epidermal lipid synthesis (Ye et al., 2002); and SC surface pH tends to become more basic (Choi et al., 2007; Hachem et al., 2005). Furthermore, in addition to activating epidermal immune response, constant exposure to toxins and/or pollutants accelerates skin aging (Vierkötter and Krutmann, 2012). Toxins present in cigarettes damage healing processes, trigger onset of diseases, increase hair loss, and cause premature skin aging and formation of deep wrinkles (Morita et al., 2009). Organic particles released by burning tobacco's smoke induce apoptosis in keratinocytes (Pedata et al., 2012). Exposure to air pollution showed significant correlation with signs of aging, such as dark spots and fine lines on the skin of 400 Caucasian women (Vierkötter et al., 2010). Moreover, capacity of response to pollutants has been suggested to diminish with age (Valacchi et al., 2012).

Active ingredients capable of regulating the immune defense function of the epidermis include those that can modulate inflammatory responses or stimulate the

synthesis of natural defense compounds, such as antimicrobial peptides. **Table 4** covers natural extracts and compounds of various origins which have been described for this type of application, such as resveratrol and its widely studied anti-inflammatory properties (for recent review, see Baur and Sinclair, 2006).

We were unable to identify any effectively proven therapeutic opportunities for epidermal regulation of toxin removal. It is therefore advisable to avoid excessive exposure to polluting or toxic substances and to pursue a healthier lifestyle. An example of this approach is a survey using future projections of the appearance of women who used tobacco led many female volunteers to stop smoking (Grogan et al., 2011). Indeed, cigarette smoking represents an environmental stressor that can damage SC, modifying its lipid composition by increasing the expression of scavenger receptor B1 (SR-B1), related to cholesterol uptake. Resveratrol was recently described as a SR-B1 inhibitor in keratinocytes in a dose-dependent manner, suggesting a skin protective potential against cigarette smoking (Sticozzi et al., 2014). Resveratrol is also able to induce phosphorylation of EGFR (epidermal growth factor receptor), whose signaling pathway regulates the expression of interleukins (IL) by human keratinocytes, such as IL-8 (Pastore et al., 2013). Moreover, in association with its natural precursor polydatin, resveratrol modulates gene expression of IL-6, IL-8 and tumor necrosis factor-alpha (TNF-α), and augments the release of human beta-defensin 2 whose combined action might mediate a positive outcome related to the skin response to toxins (Ravagnan et al., 2013).

5. Solar Radiation Protection and Antioxidant Activity

Solar radiation is a leading environmental factor that affects human skin, particularly radiation in the ultraviolet (UV) region of the spectrum, which is divided into UVA (320-400 nm), UVB (280-320 nm) and UVC (100-280 nm, mostly absorbed by the ozone layer) (Hockberger, 2002). In addition to UV rays, infrared radiation (IR, above 800 nm) may also lead to biological changes in living organisms (Polefka et al., 2012). As the amount of energy is inversely proportional to the wavelength, UVB delivers more energy than UVA. However, UVA has a higher penetration rate and reaches the deepest epidermal layers, while UVB affects primarily epidermis and papillary dermis (Hoffmann et al., 2000). UVB is harmful to biological tissues in that it causes direct injury in molecules such as nucleic acids and proteins, whereas the action of UVA is less understood and involves oxidative stress and production of reactive oxygen species (ROS) that may damage different cell components through propagation reactions (Césarini et al., 2003; Dröge, 2002; Hockberger, 2002). ROS may originate from processes such as cell respiration, or from exogenous agents such as UV radiation, which intensify the formation of such oxygen species in the skin (Burke, 2010; Palmer and Kitchin, 2010; Puizina-Ivić et al., 2010; Rahimpour and Hamishehkar, 2012). UV acts as a broad activator of cell surface receptors, inducing multiple downstream signaling pathways that regulate expression of multiple genes (Rittié and Fisher, 2002). Epidermal cells – and keratinocytes in particular – have an

internal machinery capable of preventing, to a certain extent, the occurrence of UVB-induced mutations by eliminating ROS and inducing cell cycle arrest for subsequent DNA repair. However, if the levels of accumulated damage in DNA become critical, or ROS amounts come to be excessive, an apoptosis-inducing mechanism is activated to prevent malignant changes from taking place in the cells (Kulms et al., 2002). The closer to BL, the greater the chances for a keratinocyte to undergo a malignant transformation, which is why the epidermis is endowed with additional protective mechanisms, such as pigmentation and higher cell susceptibility to UVB-induced apoptosis (Schäfer et al., 2010).

Endogenous components for the removal of ROS are in place all over the body. Transcription factor Nrf2 (NF-E2-related factor 2) is an important cytoprotector that induces production of enzymatic and non-enzymatic elements for antioxidant defense (Beyer et al., 2007; Schäfer et al., 2010). In human skin, antioxidant capacity of epidermis is much greater than that of dermis. Several antioxidant components in the epidermis have higher (enzymatic) activity or (non-enzymatic) concentration percentages than the corresponding components in dermis: superoxide dismutase (126%), glutathione peroxidase (61%), glutathione reductase (215%), glucose-6-phosphate dehydrogenase (111%), isocitrate dehydrogenase (313%), α -tocopherol (90%), ubiquinol 10 (900%), ascorbic acid (425%), uric acid (488%), reduced glutathione (513%), and total glutathione (471%) (Shindo et al., 1994).

UV radiation effects are the main cause of extrinsic skin aging or photoaging, a condition that may be aggravated when combined with IR exposure (Kligman, 1982; Polefka et al., 2012). Skin defenses against oxidative damage become vulnerable with age (Keogh et al., 1996). Elimination of DNA damage, such as removal of UVB-induced pyridine dimers, is slower in the epidermis of older individuals (Yamada et al., 2006). By the same token, antioxidant capacity of epidermal cells declines with age following reduction of α -tocopherol, ascorbic acid and glutathione concentrations (Rhie et al., 2001). As a result, aged skin shows increasing levels of oxidized proteins that become inactive and accumulate inside the cells (Sander et al. 2002).

Table 5 lists active ingredients described in the literature as capable of acting on the regulation of protection against solar radiation, as well as for their antioxidant activity. Exogenous antioxidant supplementation is currently the most explored therapeutic alternative (for review, see Dreher and Maibach, 2001). Topical and oral antioxidant use may reinforce the action of endogenous molecules in protection against ROS. Cosmetics formulated with antioxidants are among the most popular antiage products in the market worldwide (Palmer and Kitchin, 2010; Stamford, 2012). In addition, the use of sunscreens in cosmetic formulations is a preventive measure to avoid damaging effects of excessive solar radiation (for critical considerations, see Lodén et al., 2011). In view of the ample exposure of epidermis to sunlight and its fundamental role as the first barrier in the fight against

ROS, numerous studies have been investigating and proposing options of active ingredients with this protective function.

Among the widely characterized compounds that are capable of protecting skin from solar radiation are green tea extract and resveratrol (Nichols and Katiyar, 2010). Green tea extract and its main polyphenols – notably epigallocatechin-3gallate and epicatechin-3-gallate - have shown positive effects against inflammation, oxidative stress and DNA damage, with potential to nullify several biochemical processes induced or mediated by UV radiation, such as erythema and premature skin aging (Nichols and Katiyar, 2010; Türkoğlu et al., 2010). Protective effects of polyphenols were also observed due to inhibition of UVAinduced ROS production, mitogen-activating protein kinase activation, and expression of ciclooxigenase-2 (Chan et al., 2008). However, an evaluation of different commercial green tea extracts, used to enrich cosmetic formulations, revealed that photoprotective properties can be affected by the methodologies employed for production of the herbal mixtures (Silva et al., 2013). Therefore, the use of standardized extracts, at least in terms of polyphenols content, seems to be essential to assure the efficacy of products containing such ingredients. Resveratrol, another well-known antioxidant molecule (Bastianetto et al., 2010), is a phytoalexin isolated mainly from grapes (Jagdeo et al., 2010). As a very promising natural drug, resveratrol has been widely explored in the last years to fight aging and age-associated disturbes with consistent in vivo apllications (for recent review, see Baur and Sinclair, 2006) and different mechanisms of action,

including: 1) reduction of intracellular hydrogen peroxide-upregulated ROS (Jagdeo et al., 2010), 2) activation of sirtuin – in special SIRT1 that is capable of deacetylate histones promoting increased DNA stability and persistent survival in mammals – and cellular protection against UV damages via modulation of p53 and JNK pathways (Cao et al., 2009), and 3) significant cancer chemopreventive potential (Qian et al., 2009).

6. Concluding Topics and Prospects

With the growing lifespan and quality of life of the population worldwide, appearance of skin becomes increasingly important for people to feel safe and confident in their social interactions. Skin products currently in use are based on new standards of personal hygiene and health, in addition to transmitting a significant aesthetic appeal. Moreover, skin care represents an additional benefit for the elderly, since it also helps to prevent skin disorders and cancer development (Farage et al., 2008a). In its efforts to meet the escalating demand for treatments, development of products keeps abreast of the rapidly evolving knowledge of skin physiology and its functional deterioration with age. Two work fronts cooperate for these advances in knowledge: 1) identification of new biological mechanisms associated with skin aging, and 2) continuous discoveries of new forms of acting to prevent the appearance of or recover signs of aging.

New active ingredients, formulations and suitable delivery systems that may induce the recovery of biological functions affected by age are being sought both by cosmetic and pharmaceutical industries (Kaur et al., 2007). Moreover, a growing movement is under way to customize treatments by taking specific needs of each individual into account. This is the development of tailored medicine, whereby ingredients and their combinations are optimized in a unique composition intended for a specific person (Rizzo and Maibach, 2012; Squassina et al., 2010). If this movement is to become feasible for skin treatment, it would be highly useful to have an extensive portfolio of active ingredients capable of acting on cells, pathways or specific molecules, in addition to refined skin diagnoses. Lists of potential candidates for epidermal aging treatment were organized according to this innovative concept. Mechanisms of action were discussed for key ingredients, evidencing the importance of in depth scientific assessment for specific compounds before their use, considering not just individual needs, but also specific biological and physicochemical properties, compatibility with intended formulation, as well as the availability of robust pre-clinical and clinical trials.

Another scientific trend is related to a holistic approach for the treatment of skin aging. If the skin is to be viewed as a complex biological system, emergence and advance of research involving different skin layers or cell types are essential for the development of more complete and comprehensive therapies. In this sense, it is important to note that our review was focused on active ingredients available for topic applications, but new opportunities have been described for dietary

supplements. Distinct possible applications of ingredients in the treatment of phenotypes like aging gave origin to new terminologies that has been more and more difused in the market, including cosmeceuticals (topically applied products capable of making changes in the skin status that are not considered drugs, nor cosmetics, that decorate the skin), nutraceuticals (any substance that is a food or part of a food that provides medical or health benefits, including the prevention and treatment of disease), and nutricosmetics (a new concept formed by the intersection of cosmeceuticals and nutraceuticals and referring to oral supplementation of nutrients formulated and marketed specifically for beauty purposes) (Anunciato and da Rocha Filho, 2011). This nomenclature is not aligned across legal regulations in different countries but, independently of the adopted term, it points to a trend that involves the development of interdisciplinary activities focused on health and well-being promotion (Anunciato and da Rocha Filho, 2011; Vranesić-Bender, 2010). A good example of that is the use of probiotics for improvements in the photoprotection capacity of the skin (Guéniche et al., 2009). Supplementation with the oral probiotic bacteria Lactobacillus johnsonii (La1) maintains cutaneous immune homeostasis after UV exposure, evidenced through substantial experimental protocols, including randomized, double-blind and placebo controlled clinical trials (Guéniche et al., 2006 and 2008; Peguet-Navarro et al., 2008; Yang et al., 2011). If combined with nutriotinal doses of carotenoids, La1 intake reduced early UV-induced skin damage, suggesting a beneficial influence on skin photoaging (Bouilly-Gauthier et al., 2010). Cutaneous carotenoids can be enriched in the skin by nutrition and topically applied antioxidants, indicated

for the prevention of cell damage, premature skin aging, and skin cancer (Meinke et al., 2013). Indeed, anti-aging substances derived from food includes different categories of ingredients, but special attention has been dedicated to those with antioxidant properties, such as coenzyme Q10, phytoestrogens, probiotics and omega-3 fatty acids (Vranesić-Bender, 2010).

This work addresses the issues specifically associated with epidermal aging and was conducted with the intention of providing a comprehensive list of therapeutic approaches to complement those that are currently in use and chiefly concerned with the dermis. This scientific scenario is undergoing rapid expansion with opportunities for future developments. Growing advances in research in the fields of molecular biology and skin stem cells are examples of the next steps to be taken by cosmetology and dermatology (Fu and Sun, 2009). For many of actives considered here, well controlled and executed efficacy and safety studies in man are few or none. The integrity of interpretation of these therapeutic and/or preventive actions will – in the end – rest on such information.

Conflict of Interest

No conflict of interest was involved in the present work.
Figure captions

Figure 1. Molecular, cell and morphological changes associated with epidermal aging. As the epidermis ages, it undergoes a series of structural modifications (Bergman et al., 2000; Choi et al., 2007; Chu and Kollias, 2011; Denda et al. 2003; Hachem et al., 2005; Levakov et al., 2012; Scharffetter-Kochanek et al., 2000; Zouboulis and Makrantonaki, 2011) that directly impact its physiological functions, compromising the natural protective barrier of the organism. Diagram indicating calcium distribution points to a higher ion concentration in the granular layer (GL), darker colored, region in young epidermis (1). In older epidermis (2) calcium gradient is lost and calcium is possibly distributed homogeneously among the skin layers. Possible therapeutic alternatives are different forms of action of active ingredients or compounds capable of helping to recover age-affected physiological functions to an extent that will approximate them as nearly as possible to those in young epidermis.

Table 1. Active ingredients for regulation of epidermal protection barrier against

mechanical and chemical insults.

Active Ingredients	Action Mechanisms	References
Achillea millefolium extract*	As the human epidermis ages, expression of receptors of PMOC, a precursor of neuropeptides including ACTH and β -endorphin, gradually diminishes. In human keratinocytes, <i>A. millefolium</i> extract increased the synthesis of mRNA and proteins for POMC, MC-2R e MOR-1 receptors. In biopsies of skin in culture, the extract helped to improve the expression of K10, transglutaminase-1 and filaggrin, and to increase epidermal thickness. In vivo, it improved appearance of wrinkles and pores significantly in comparison with placebo.	Pain et al., 2011
Adapalene*	Adapalene is a synthetic retinoid commonly used in acne treatment. In vitro and in vivo studies found it active in the regulation of epidermal cell proliferation and differentiation. Action of adapalene on keratinocytes takes place via RAR – specifically γRAR.	Jain, 2004; Michel et al., 1998
Alpha-hydroxy acids*	AHA's are widely used in chemical peeling and cosmetic formulations as cell renewal stimulants. A lotion containing 25% of AHA promoted a 25% increase in skin thickness as well as a reduction in melanin content, which diminished skin spots. Treatment with glycolic acid increased epidermal cell proliferation rate and thickness in mice, as well as the nuclear volume of keratinocytes in the basal, spinous, and granular layers. Treatment with lactic acid results in increased firmness and thickness of both the epidermis and the dermis, as well as clinical improvement in the softness of the skin and in the appearance of fine lines and wrinkles.	Babilas et al., 2012; Bhattacharyya et al., 2009; Ditre et al., 1996; Smith, 1996; Yamamoto et al., 2006
Arotinoid ethyl ester	AEE stimulated cell proliferation in the epidermis of embryonic and adult mice. AEE inhibited epidermal differentiation in embryonic mice and stimulated it in the adult animal.	Tsambaos et al., 1985
Ethyl-α-D-glucoside	a-EG, the main component in Japanese sake, increases loricrin content significantly by acting on keratinocyte differentiation, while reducing the number of SC layers in aged mice, improving their functionality.	Nakahara et al., 2007

Green tea polyphenols	Green tea polyphenols, especially EGCG, were tested on primary human keratinocytes and stimulated their proliferation and differentiation via induction of p57/KIP2, with higher expression of K1 and filaggrin and increased transglutaminase activity. In aged keratinocytes with reduced cell activity rates, treatment with green tea polyphenols renewed DNA synthesis and succinate dehydrogenase activation. EGCG also exhibited a potential for the modulation of caspase 14, a unique regulator of terminal differentiation of keratinocytes associated with cornification.	Hsu et al., 2005 and 2003
Hesperidin	Hesperidin is found in orange rind extract. Its topical application on mice stimulated proliferation, differentiation and secretion of lamellar bodies in the epidermis, as well as activation of PPAR- α and PPAR- γ in keratinocytes.	Hou et al., 2012
Hyaluronic acid*	HA has been extensively studied in epidermal renewal as a component of formulations, or injected intradermically as an alternative antiage treatment. There are also treatments with active ingredients that induce HA production in the skin, as well as research on the therapeutic potential of HA with different molecular weights. A regimen of topical treatment with low molecular weight HA followed by high molecular weight HA increases proliferation and epidermal thickness, and stimulates cell differentiation in aged mice skin. HA acts on CD44 activation, inducing a series of effects on epidermal processes via Rho GTPase.	Bourguignon et al., 2013; Farwick et al., 2011
Jasmonic acid derivative (LR2412)	Treatment with LR2412 induces hyperplasia in epidermis reconstructed in vitro, with an increase in Ki67-positive cells and in epidermal thickness. LR2412 also stimulates HAS2 and HAS3 expression, as well as HA deposition. Treatment with this compound did not modify the expression of the main proteins involved in late terminal differentiation steps, such as filaggrin e transglutaminase 1, indicating that it is devoid of skin irritant potential.	Michelet et al., 2012
Imiquimod*	Therapy using 5% IMI for actinic keratosis results in less compact hyperkeratosis, more homogeneous pattern of epidermal crystals, ordered epidermal proliferation, less sun-damaged melanocytes, and better overall aspect of the skin.	Smith et al., 2007
L-fucose	Percutaneous application of 1% L-fucose in rats during four weeks results in increased skin thickness in 13% of the test group, in addition to significant improvements in the dermis.	Fodil- Bourahla et al., 2003
Lutein	Lutein, zeaxanthin and astaxanthin induced increased expression of HAS3, with an increase in hyalurinan synthesis. Lutein significantly increased RARE transcript activity. In addition, lutein-derived metabolites were reported to act as RAR ligands in keratinocytes, which makes lutein a potential substitute for retinoids.	Sayo et al., 2013

Myristyl nicotinate*	MN, a nicotinic acid derivative, was developed for treating photodamaged skin. Treatment of photodamaged face skin increases the content of NAD in the skin by 25%, in addition to increasing the stratum corneum thickness by 70% and of the whole epidermis by 20%. MN causes the epidermal renewal rate to increase by 6 to 11% and the TEWL rate to decrease by about 20%. These results indicate that MN improves differentiation and epidermal barrier function, suggesting that MN can play a significant part in the treatment of the progression of skin lesions caused by photoexposure.	Jacobson et al., 2007
Oxysterols	Treatment of primary human keratinocytes with oxysterols induced differentiation, stimulating the expression of involucrin and transglutaminase with an inhibitory effect on cell proliferation. Action pathway of oxysterols in the keratinocytes involves activation of liver X receptor-beta. Similar results have been obtained from topical treatments of mice with oxysterols, indicating increased levels of mRNA and protein for involucrin, loricrin and profilaggrin. The treatment of hyperproliferative epidermis with oxysterols proved capable to restore epidermal homeostasis.	Hanley et al., 2000; Kömüves et al., 2002
p- Dodecylaminophenol	With a more potent antioxidant action than retinoic acid, p-DDAP suppresses MMP expression and stimulates K16 synthesis without causing skin irritation or desquamation. p-DDAP also regulates keratinocyte differentiation, promotes increase in epidermal thickness, and may improve wrinkles and freckles in mice.	Takahashi and Fujiu, 2010
Retinyl retinoate*	Retinyl retinoate is a less irritating retinol derivative than other retinoids. A study of primary human and mice keratinocyte cultures indicates that retinyl retinoate has a potential for expressing retinoic acid, as well as its receptor CD44 and the enzyme HAS2.TEWL rates induced by retinyl retinoate were lower than the rates induced by retinol, retinoic acid and retinaldehyde. When used in topical formulations, retinyl retinoate decreased wrinkles.	Kim et al., 2011 and 2010
Simarouba amara extract*	Immunohistochemical analysis of involucrin and activation of transglutaminase in skin fragments treated with this extract demonstrated its potential to increase the expression of these markers. Results were proven with clinical and instrumental methodologies which showed it to have an effect on the improvement of barrier function and skin hydration.	Bonté et al., 1996
Triterpenes*	Purified TE's particularly rich in betulin were demonstrated to act on the proliferation, apoptosis and differentiation of human keratinocytes in vitro, ex vivo, and in vivo. TE activity in human keratinocytes occurred by means of increased calcium influx, which led to an increase in the expression of genes such as TRPC6 and several differentiation markers, including K10.	Woelfle et al., 2010

Valproic acid	Application of VPA on lesions in the skin of mice assisted the scarring process by stimulating the expression of β -catenin and terminal differentiation markers in keratinocytes, as well as the expression of proliferation markers such as Ki67. In vitro, VPA increased the mobility of HaCaT-lineage keratinocytes by activating signaling pathways involving Wnt/ β -catenin, ERK and Pl3-kinase/Akt.	Lee et al., 2012
Vitamin A*	Vitamin A or retinoic acid is the most widely studied compound for epidermal renewal because of its effect on the proliferation and differentiation of keratinocytes. However, there have been reports of instability and degradation in cosmetic formulas, and also of incidence of skin irritation, prompting the production of similar compounds to avoid such unwanted effects. Retinoids are lipophilic molecules that penetrate easily in the epidermis; their biologically active forms modulate the expression of genes involved in cell differentiation and proliferation by way of nuclear receptors. Mechanisms of retinoid action include RAR and RXR activation, increased CRABP2 and HBEGF gene expression, enhanced keratinocyte proliferation, and increased epidermal thickness. Their proliferative effect was also noted in human keratinocytes via P2Y2 activation.	Babamiri and Nassab, 2010; Bellemère et al., 2009; Fujishita et al., 2006; Sorg et al., 2006 and 2005; Tur et al., 1995; Wang et al., 2011
Vitamin B3*	Topical application of vitamin B3 (niacinamide or nicotinic acid), has a stabilizing effect on the epidermal barrier function by reducing TEWL and improving the moisture content of the cornified layer. Niacinamide leads to increased synthesis of proteins with keratin, stimulation of ceramide synthesis, acceleration of keratinocyte differentiation, and increased intercellular NADP levels. In skin aging treatments, topical application of niacinamide results in improvement of skin surface structure, softening of wrinkles, and photocarcinogenesis inhibition.	Gehring, 2004

* Active ingredients with placebo/vehicle controlled studies in vivo in man. a-EG (ethyl-a-D-

glucoside), ACTH (adrenocorticotropic hormone), AEE (arotinoid ethyl ester), AHA (alphahydroxy acids), Akt (a serine/threonine-specific protein kinase), CD44 (cluster of differentiation 44), CRABP2 (cellular retinoic-acid-binding protein II), EGCG (epigallocatechin-3-gallate), ERK (extracellular-signal-regulated kinases), HA (hyaluronic acid), HAS (hyaluronan synthase), HBEGF (heparin-binding epidermal growth factor), IMI (imiquimod), K (keratin), Ki67 (nuclear protein Ki-67), MC-2R (melanocortin 2 receptor), MMP (matrix metalloproteinases), MN (myristyl nicotinate), MOR-1 (µ-opioid receptor), NAD (nicotinamide adenine dinucleotide), NADP (nicotinamide adenine dinucleotide phosphate), P2Y2 (P2Y purinoceptor 2), p57/KIP2

(cyclin-dependent kinase inhibitor), p-DDAP (p-Dodecylaminophenol), POMC (proopiomelanocortin), PPAR (peroxisome proliferator-activated receptor), PI3 (phosphatidylinositol TRPC6 (transient receptor potential canonical subtype 6), VPA (valproic acid), Wnt (a group of

Table 2. Active ingredients in epidermal regulation for maintenance of water-ion

balance in the organism.

Table 2

Active Ingredients	Action Mechanisms	References
Ajuga turkestanica hydroalcoholic extract*	A. turkestanica extract increased AQP3 and filaggrin expression compared with non-treated groups in studies with experimental human keratinocyte models and cocultures of human keratinocytes and fibroblasts. These results led to the application of the extract in formulations; a significant increase hydration was observed in human skin, which strengthens the role of these water channels and small solutes in the skin as a regulation mechanism for the hydration of the skin.	Dumas et al., 2007 and 2002
Botryococcus braunii microalgae	Extract of these microalgae increased significantly the AQP3 gene expression in human keratinocyte cultures in vitro. Furthermore, it inhibited hormone-sensitive lipase activity in adipocytes and increased the biosynthesis of collagen I and III in fibroblasts. To an important extent, the extract increased expression of cornified envelope proteins, such as filaggrin and involucrin, and exhibited a powerful antioxidant activity, for example in reducing nitric oxide production.	Buono et al., 2012
Coffea arabica L. seed oil	C. arabica L. seed oil induces TGF-β and GM-CSF increase in cell culture; both are associated with increased synthesis of extracellular matrix and recovery of neurological response, and also with increased AQP3 gene expression in culture and ex-vivo skin.	Velazquez Pereda et al., 2009
Eucalyptus extract (standardized in macrocarpal A)*	Addition of eucalyptus extract to a culture of human keratinocytes increased ceramide levels in a dose- dependent manner, as well as glucosylceramide and sphingomyelin biosynthesis. Topical application of the extract on dry human skin promoted increase in SC ceramide levels, reduction of TEWL, and improved barrier function of the skin. Addition of macrocarpal A, the chief phytochemical in eucalyptus extract, promoted an increase in the amount of ceramide, as well as the expression of acid palmitoyl-transferase, sphingomyelinase, glucosylceramide synthase and glucocerebrosidase. Results indicate a possible therapeutic application of this extract for a variety of skin disorders.	lshikawa et al., 2012
Glycerol*	Glycerol promotes a significant increase of AQP3 and AQP10 gene expression in human keratinocyte culture in vitro. Moreover, in skin exposed to UVB radiation, which reduces the presence of these proteins in the skin, glycerol has been shown to promote the preservation of this expression, contributing to the maintenance of hydric homeostasis in the skin when confronted with this type of environmental aggression.	Jungersted et al., 2013; Lodén and Maibach, 1999; Xie et al., 2013

Gypsum fibrosum extract (standardized in 0.3% of CaSO₄)	Animals treated with oral doses of 0.3% <i>G. fibrosum</i> extract or 0.3% of CaSO ₄ revealed a significant increase in AQP3 expression relatively to non-treated groups. This shows that both the extract and its main active ingredient by itself are capable of stimulating AQP3 expression, contributing positively to the maintenance of hydric homeostasis in the skin.	lkarashi et al., 2012
Kanglaite (mixture of extractions of coix seed)	In a photoaging study using different experimental models, including in vitro and skin-equivalent models, kanglaite increased AQP3 gene expression. It was also capable of inhibiting the reduction of the expression of this protein caused by keratinocyte exposure to UVB radiation.	Shan et al., 2012
Lithospermum erythrorhizon aqueous extract	Aqueous gromwell (<i>L. erythrorhizon</i>) extract induced more intense keratinocyte and fibroblast migration with increased lipid synthesis in an experimental model that simulates wound healing. Cell groups treated with the extract showed a significant increase in phospholipids, sphingolipids (ceramides and glucosylceramides), and neutral lipids. These findings indicate that the aqueous <i>L.</i> <i>erythrorhizon</i> extract has an important mechanism linked to the improvement of barrier function and consequent maintenance of skin hydration.	Kim et al., 2012a
Natural oils, waxes or derivatives*	There are countless available possibilities of using natural compounds whose lipid composition mimics SC elements, or else acts as an adjutant in skin hydration. The following stand out: amaranth oil, apricot oil, argan oil, candelilla wax, canola oil, carnauba wax, castor oil, coconut oil, corn oil, jojoba oil, jojoba wax, lanolin, lecithin, olive oil, palm oil, rice bran oil, safflower oil, sesame oil, shea butter, soybean oil, squalane, sunflower oil, sweet almond oil, wheat-germ oil, and yellow beeswax, among others.	Budai et al., 2012; de Waroux Yle, 2013; Huang et al., 2009
Piptadenia colubrina extract*	<i>P. colubrina</i> hydroglycolic extract, standardized for total arabinogalactans, increased AQP3 gene and protein expression in keratinocyte culture and ex-vivo skin. Extract also increased the expression of the cornified envelope proteins filaggrin and involucrin. These skin-hydration related results were substantiated with findings from clinical studies, in which formulations containing the extract increased the corneometric indices and reduced TEWL.	Pereda et al., 2010

Rice-derived glucosylceramide	Rice-derived GCFr significantly changed the SC ceramide profile in a human skin-equivalent model. Oral administration of this GCFr fraction in mice (3 and 10 mg/kg/day) reduced TEWL in the group exposed to sodium lauryl sulfate. In the skin fragments, ceramide I had increased, while GlcCer (EOS) and the mixture of the GlcCer + GlcCer A/B complex had diminished. These shifts were followed by an increase in GCSase and glucocerebrosidase expression. On the other hand, the expression of GlcCer (d18:2), ceramides 1 and 2, GlcCer (EOS), and GlcCer A/B increased in skin equivalent and was followed by the expression of GCSase and epidermal maturation markers for these ceramides. These results suggest that oral administration of GCFr counterbalanced epidermal ceramide loss by increasing GlcCer metabolism, which resulted in TEWL reduction and barrier function improvement.	Shimoda et al., 2012
Simarouba amara extract*	Immunohistochemical analysis of skin fragments treated with <i>S. amara</i> extract demonstrated an increase in involucrin expression and transglutaminase activation. These results were corroborated by clinical and instrumental methodologies which provided evidence of effects related to improvement of barrier function and skin hydration.	Bonté et al., 1996
Urea*	Urea was shown to stimulate significantly the expression of AQP3, AQP7 and AQP9, as well as of cornified envelope proteins (filaggrin, loricrin and involucrin), in addition to promoting increase in the activity of transglutaminase-1 and other enzymes involved in skin lipid synthesis.	Grether-Beck et al., 2012; Lodén and Maibach, 1999

* Active ingredients with placebo/vehicle controlled studies in vivo in man. AQP (aquaporin),

GCSase (glucosylceramide synthase), GlcCer (EOS) (esterified $\omega\text{-hydroxy}$ fatty acid and

sphingosine [EOS]), GM-CSF (granulocyte-macrophage colony-stimulating factor), GCFr

(glucosylceramide fraction), SC (stratum corneum), TGF- β (transformation growth factor β),

TEWL (transepidermal water loss), UVB (ultraviolet B).

Table 3. Cytokines produced by epidermal cells, with constitutive or induced

expression.

Cells	Cytokines
Keratinocytes	G-CSF, GM-CSF, IFN-γ, IL-1α, IL-1β, IL-3, IL-6, IL-7, IL-8, IL-10, IL-12, IL- 15, IL-18, IP-10, M-CSF, MCP-1, MIP-1α, TGF-α, TGF-β, TNF-α
Langerhans Cells	IFN-γ, IL-1α, IL-1β, IL-6, IL-15, IL-18, MIP-1α, MIP-2, TGF-β
Melanocytes	G-CSF, GM-CSF, IL-1α, IL-1β, IL-6, IL-7, IL-8, IL-10, IL-12, MCSF, MIP-1α, MCP-1, TGF-α, TGF-β, TNF-α

stimulating factor), IFN (Interferon), IL (interleukin), IP (IFN-γ inducible protein), M-CSF (macrophage colony-stimulating factor), MCP (monocyte chemoattractant protein), MIP (macrophage inflammatory protein), TGF (transformation growth factor), TNF (tumor necrosis factor).

Table 4. Active ingredients regulating epidermal immunological defense.

Active Ingredients	Action Mechanisms	References
Association of standardized Pfaffia paniculata, Ptychopetalum olacoides B. and Lilium candidum extracts	Association of standardized plant extracts of <i>P. paniculata, P. olacoides</i> B. and <i>L. candidum</i> promotes significant anti-inflammatory action by reducing PGE2, LTB4 and histamine production in a model of cultivated normal human keratinocyte cells stimulated with LPS.	Eberlin et al., 2009
Butea monosperma (Lam.) Taub. flowers extract	Hydroglycolic <i>B. monosperma</i> flower extract is capable of reducing secretion of pro-inflammatory cytokines IL- 1 β , IL-6 and IL-8 in cell culture of normal human keratinocyte by approximately 32, 33 and 18%, respectively. In addition, the extract also inhibits the production of PGE2 and secretion of MMP-1, MMP-2, MMP-9 e MMP-10.	Krolikiewicz- Renimel et al., 2013
Coffea arabica L. seed oil	C. arabica L. seed oil induces increase of TGF- β and GM-CSF in keratinocyte cell culture; both are associated with increased extracellular matrix synthesis and immune response recovery.	Velazquez Pereda et al., 2009
Imiquimod	Topical application of imiquimod in a murine model revealed a potential for recovery of the epidermal barrier following treatment with tacrolimus. The potential was determined by stimulating IL-1 α production, and also by an increase in the gene expression of mBD3 and CRAMP, two important antimicrobial peptides.	Jung et al., 2011
Korean red ginseng extract	Treatment of human keratinocyte cells with Korean red ginseng extract indicated its capability to control LPS- stimulated inflammatory response with a dose- dependent decrease of TNF- α and IL-8 production.	Hong and Lyu, 2011
Leontopodium alpinum extract	L. alpinum extract inhibited IL-8, IP-10, MCP-1, GM-CSF, TNF- α , and IFN- γ levels, dose-dependently, in human keratinocyte cell cultures exposed to radiation or LPS. Results demonstrate anti-inflammatory and immunomodulating activities of this extract.	Daniela et al., 2012
Natural extracts of arnica flowers, betel nuts, black elder bark, and mugwort root	Natural extracts of arnica (<i>Arnica montana</i>) flowers, betel (<i>Areca catechu</i>) nuts, black elder (<i>Sambucus nigra</i>) bark, and mugwort (<i>Artemisia vulgaris</i>) root stimulated gene expression of defensins (hBD2 and/or hBD3) in a normal human keratinocyte culture model. In some cases or at specific concentrations, the extracts also induced secretion of cytokines, including MIP-3a, IL-8, and IL-1a.	Pernet et al., 2005

Red orange extract	Red orange extract (<i>Citrus sinensis</i> varieties: Moro, Tarocco, Sanguinello) has high levels of anthocyanins, flavanones, hydroxycinnamic acids, and ascorbic acid. Its anti-inflammatory activity was assessed in human keratinocytes (lineage NCTC 2544) exposed to IFN- γ and histamine. Treatment with red orange extract at different concentrations inhibited expression of ICAM-1 and secretion of MCP-1 and IL-8.	Cardile et al., 2010
Resveratrol*	Resveratrol or its natural precursor, polydatin, on human keratinocytes (lineage HaCaT) promoted the modulation of gene expression of cytokines IL-6, IL-8, and TNF- α , and also stimulated the expression of Hsp70B (important for cytoprotection and cell repair) and hBD2.	Baur and Sinclair, 2006; Ravagnan et al., 2013

* Active ingredients with placebo/vehicle controlled studies in vivo in man. CRAMP (cathelin related antimicrobial peptide), GM-CSF (granulocyte-macrophage colony-stimulating factor), Hsp (heat shock protein), hBD (human beta defensin), ICAM-1 (intercellular adhesion molecule 1), IFN-γ (Interferon γ), IL (interleukin), LPS (lipopolysaccharide), LTB4 (leukotriene B4), mBD (mouse beta-defensin), MCP-1 (monocyte chemoattractant protein-1), MIP-3a (macrophage inflammatory protein 3a), MMP (matrix metalloproteinases), PGE2 (prostaglandin E2), TGF-β (transformation growth factor β), Th (T helper cell), TNF-α (tumor necrosis factor α).

Recei

Table 5. Active ingredients for regulation of epidermal protection against solar

radiation and antioxidant activity.

Active Ingredients	Action Mechanisms	References
Astaxanthin*	Astaxanthin, derived from the microalga Haematococcus pluvialis and administered both orally and topically in humans, provided significant inhibition of melanogenesis in age spots by suppressing oxidative melanocyte polymerization and inflammation of the epidermis. Treatment with astaxanthin also acts by protecting keratinocytes from differentiation and cornification induced by oxidative damage.	Tominaga et al., 2012
Apigenin and luteolin	Apigenin and luteolin jointly inhibited the production of ROS in, and increased the viability of, HaCaT cells irradiated with UVA. Pretreatment of the keratinocytes with these flavonoids also inhibited UVA-induced production of MMP-1 and suppressed the expression of c-jun and c-fos, as well as MAPK phosphorylation. Flavonoids also diminished the calcium influx and Ca2+/CaMKs phosphorylation.	Hwang et al., 2011
β-carotene	β -carotene inhibited UVA-induced gene modulation in a HaCaT human keratinocyte lineage. In non-irradiated cells, the gene regulation suggests that β -carotene significantly reduced signs of stress and degradation of the extracellular matrix, in addition to promoting the differentiation of the keratinocytes. These effects occur via singlet oxygen sequestration.	Wertz et al., 2005
Calluna vulgaris extract	Topical application of <i>C. vulgaris</i> extract (4 mg polyphenols/cm ²) on mice during 30 minutes before exposure to UVB radiation, for 10 days, provided protection to the skin, reducing the levels of TNF- α and IL-6 cytokines and pirimidin dimers, and the formation of UVB-induced sunburn cells. Therefore, <i>C. vulgaris</i> extract protects the skin from sun-induced DNA damage.	Olteanu et al., 2012
Cocoa powder*	Female volunteers who took these flavonoids during 12 weeks showed reduced UV radiation-induced erythema, improved skin appearance and hydration, increased skin layer thickness, and lower TEWL.	Heinrich et al., 2006; Katz et al., 2011
Cynaropicrin	Cynaropicrin prevents photoaging of micel by suppressing photo-induced (especially UVB radiation- induced) transactivation of NF-kB.	Tanaka et al., 2013
Epicatechin-3-gallate	ECG inhibits keratinocyte death induced by UVA and UVB in a dose-dependent manner. For UVA, this mechanism proceeds by inhibiting hydrogen peroxide production. For UVB, ECG inhibited membrane lipid peroxidation in treated cells, in addition to blocking the activation of ERK1/2, p38 and JNK in keratinocytes. Therefore, ECG was demonstrated to have an important antioxidant potential to prevent photodamage.	Huang et al., 2007 and 2005; Nichols and Katiyar, 2010

Epigallocatechin-3- gallate*	EGCG promotes keratinocyte survival and inhibits UV- induced apoptosis with the aid of a dual mechanism: 1) increased Bad phosphorylation through ERK-AKT- dependent pathways; 2) increased Bcl-2/Bax ratio. EGCG treatment of human HaCaT keratinocyte cultures lowered UVB-induced cytotxicity and also inhibited mRNA expression of apoptosis-regulating genes p53 and p21, and gene c-fos, in addition to blocking the secretion of cytotoxins IL-6 and TNF-a. These data suggest that EGCG may be used for its antiaging effect and as a tumoral inhibitor in human skin. Moreover, EGCG can inhibit/regulate NF-kB action, iNOS gene expression, and NO generation in keratinocytes following UVB exposure. It suggests that EGCG may have an inhibitory effect on photodamage caused by UVB in the epidermis. In human in vivo evaluation, the addition of EGCG to a broad-spectrum sunscreen decreased UV- induced damage compared with sunscreen alone.	Chen et al., 1999; Chung et al., 2003; Luo et al., 2006; Matsui et al., 2009; Song et al., 2006; Tobi et al., 2002
Fucoxantin	Fucoxantin antioxidant activity inhibited vessel formation induced by UVB exposure in a hairless mice model. Expression of VEGF abates with reduction in wrinkle formation, diminishing epidermal hypertrophy caused by UV exposure.	D'Orazio et al., 2012; Urikura et al., 2011; Yasuda et al., 1999
General carotenoids*	Raman spectroscopy showed that, as a defense mechanism against harmful irradiation and environmental factors, topical application of carotenoids enhances the defense potential of the human epidermis. In addition, carotenoids are recognized as excellent nutricosmetics, improving skin resilience and hydration.	Anunciato and da Rocha Filho, 2011; Darvin et al., 2009; Lademann et al., 2011
Grape seed proanthocyanidins	Human keratinocytes irradiated with UVB and treated with GSP's inhibited formation of UVB-induced hydrogen peroxide, lipid peroxidation, protein oxidation, DNA damage, as well as depletion of antioxidant components, such as glutathione peroxidase, catalase, superoxide dismutase, and glutathione. GSP's also inhibit phosphorylation of ERK1/2, JNK, p38 and proteins of MAPK family, as well as UVB-induced activation of NF- kB/p65. These results suggest that GSP may attenuate UV-induced oxidative stress in human skin.	Mantena and Katiyar, 2006
Green tea extract*	Green tea extract enhances skin photoprotection through anti-inflammatory, antioxidant, and DNA repair mechanisms. In mice stimulated by psoralen and UVA (a quite common psoriasis treatment), orally-administered green tea extract inhibited c-fos and p53 protein accumulation. In reconstituted skin model, green tea extract inhibited psoralen plus UVA-induced 8- methoxypsoralen-DNA adduct formation and p53 protein accumulation. Topic treatment of human skin with green tea extract lowered UV-induced p53 expression as well as the number of apoptotic keratinocytes.	Mnich et al., 2009; Nichols and Katiyar, 2010; Zhao et al., 1999
Jacquez grapes wine extract	Jacquez grapes wine extract efficiently prevents the skin from suffering oxidative damage induced by exposure to UVB radiation. This photoprotective effect is attributed to the rich polyphenol content of the extract. Its application, tested on reconstituted skin, helps to maintain the epidermal redox state even after exposure to radiation.	Tomaino et al., 2006
--	---	---
L-carnosine and Rhodiola rosea extract association	This association of extracts modulates β -endorphin, enkephalin, CGRP, substance P, IL-1 α , TNF- α and IL-10 levels in normal human keratinocytes in basal conditions, as well as under conditions of acute or chronic exposure to UV radiation.	Dieamant et al., 2008
Lycopene*	Employed in several formulations for topical use, lycopene shows hight therapeutic potential to recover epidermal antioxidants lost as a result of UV exposure and, in addition, acts to protect the skin from damage caused by UV. Lycopene was also found to work as a preventive agent by inhibiting the activity of epidermal omithine decarboxylase, reducing inflammation, maintaining cell proliferation at normal levels and, possibly, preventing damage to DNA from apoptosis blockage (in particular by inhibition of caspase-3), after exposure to UVB.	Andreassi et al., 2004; Fazekas et al., 2003
<i>Mangifera indica</i> L. extract	Mice treated orally with mango (<i>M. indica</i> L.) extract exhibited a significant capacity to modulate harmful effects of UV radiation by inhibiting epidermal hypertrophy.	Song et al., 2013
Mangiferin	Mangiferin is a sequestrant of ROS, superoxide radicals, and hidroxyl radicals. In HaCaT human keratinocyte cultures, mangiferin inhibited the induction of MMP-1 generated by hydrogen peroxide, blocking AP-1 DNA binding. In addition, mangiferin inhibited keratinocyte cell death by down-regulating MEK-ERK and SEK-JNK pathways.	Chae et al., 2011
Myricetin	Myricetin inhibits UVB-induced human keratinocyte death in a dose-dependent fashion, by inhibiting hydrogen peroxide build-up and c-jun activation induced by UVB.	Huang et al., 2010
N-acetyl cysteine and genistein*	Pretreatment of human skin with N-acetyl cysteine in conjunction with genistein blocked UV-induction of collagenase, indicating a photoprotective potential for this ingredient.	Kang et al., 2003
Naringenin	Treatment of HaCaT human keratinocytes with naringenin extended the long-term survival of the cells after irradiation with UVB. UVB-induced PARP-1 cleavage, caspase activation, and Bax/Bcl2 ratio were modulated after the naringenin treatment, indicating an antiapoptotic effect for this active ingredient. Also, when HaCaT cells are irradiated with UVB, naringenin increases CPD removal, which indicates that the active ingredient has a protective effect against DNA damage.	El-Mahdy et al., 2008

Phenylpropanoid glycosides	Phenylpropanoid glycosides (verbascoside, forsythoside B, echinacoside and campneoside I) induced Nrf2 and cytoprotective enzyme activity, and exhibited antioxidant activity in HaCaT human keratinocyte cultures.	Sgarbossa et al., 2012
Polyphenol-rich pomegranate fruit extract	POMx effect on photoaging and UVB-induced oxidative stress was evaluated on HaCaT human keratinocytes. Pretreatment with POMx modulated UVB effects related to reduction in cell viability and intracellular glutathione content, and increase in lipid peroxidation. POMx was also capable of inhibiting increases in MMP-1, -2, -9, and -7, reduction of TIMP-1, and UV-induced phosphorylation of MAPK and c-jun.	Zaid et al., 2007
Polypodium leucotomos exctract	Oral administration of <i>P. leucotomos</i> extract in mice during 5 days prior to UV exposure and 2 days following irradiation reduced the number of proliferating cells in the epidermis by 13%, promoted an increase in p53-positive cells, and increased the antioxidant capacity of plasma by 30%. The beneficial effect of <i>P. leucotomos</i> extract is probably due to its antioxidant and anti-ROS properties.	Rodríguez- Yanes et al., 2012
Red orange extract	Red orange extract was able to neutralize UVB-induced response efficiently in HaCaT human keratinocytes and, in particular, some of the events associated with inflammation and apoptosis, such as NF-kB and AP-1 translocation and procaspase-3 cleavage. This activity is probably due to a blockage of events related to cell oxidative stress, showing that red orange extract may be useful for the photoprotection of the skin.	Cimino et al., 2007
Resveratrol*	Human skin has specific bonding sites for resveratrol, which has a potential to delay, or even arrest, the normal course of skin aging by blocking apoptotic events and mitochondrial disfunctions in keratinocytes. Studies with the HaCaT human keratinocyte lineage have shown trans-resveratrol to be able to inhibit hydrogen peroxide production. In humans, in addition to providing a protective effect against UVA radiation, trans-resveratrol even improves clinical signs of aging when used in association with β -cyclodextrin excipient.	Bastianetto et al., 2010; Baur and Sinclair, 2006; Chen et al., 2006; Moyano- Mendez et al., 2013
Rheum rhaponticum L. rhizome extract	Rhubarb extract (<i>R. rhaponticum</i> L.) showed antiradical characteristics and antioxidant properties against lipid peroxidation in vitro; the extract also reduced tirosinase activity. In addition, it inhibited the production of IL-1 α , TNF- α , and α -MSH, and the activity of tyrosine kinase in human melanocytes subjected to UV radiation.	Silveira et al., 2013
Sea buckthorn fruit blend	UV-irradiated mice were treated orally with a blend of sea buckthom fruit extract, blueberry extract and collagen. Oral ingestion of SFB reduced formation of wrinkles and helped to maintain skin thickness. SFC- treated mice showed inhibited TEWL and increased skin moisture content. SFB application reduced MMP-1 and - 9 expressions, and regulated SOD activity levels.	Hwang et al., 2012

Silk lutein	Protection against harmful effects of UVB was evaluated for lutein extracted from yellow silk cocoons, in comparison with plant-derived lutein, in primary human keratinocytes or lineage CCD 1102 KERTr. Silk lutein was not cytotoxic for keratinocytes, and also protected the cells that received treatment prior to UVB iradiation, reducing the cytotoxicity and the levels of cell apoptosis.	Pongcharoen et al., 2013
Soybean extract	Soybean extract, rich in isoflavones, inhibited UVB- induced cell death in HaCaT human keratinocytes, as well as p38, JNK and ERK1/2 phosphorylation. In mice, topic application prior to UV irradiation was shown to diminish epidermal thickness and COX-2 and PCNA expression, and also to increase catalase concentration.	Chiu et al., 2009
Tannase-converted green tea extract	Tannase, an enzyme produced by fungi, yeasts and bacteria, hydrolyzes catechin gallates (EGCG and ECG) from green tea and enhance its potential application for elimination of radicals, such as hydrogen superoxide and peroxide. A formulation containing tannase-converted green tea extract was used to inhibit UV-induced oxidative damage in mice epidermis. Formulation acted by preventing glutathione reduction and controlling hydrogen peroxide levels. Mice treated with FTGE displayed a significant reduction in the levels of thiobarbituric acid reactive substances by lipid peroxidation, in comparison with non-UVB-irradiated controls, which indicates that this formulation is effective in protecting the skin against photoaging.	Hong et al., 2012
Tectroside	Tectroside or lactone inhibits UVB-induced production of proinflammatory cytokines (IL-6 and IL-8) in HaCaT human keratinocyte cultures, in a dose-dependent manner. It also inhibits COX-2 expression and JNK phosphorylation. These results suggest that this compound has the potential to protect the skin against UVB-induced inflammation.	Kim et al., 2013
Vitamin C*	Vitamin C or ascorbic acid reduces effects of aging, such as deep and superficial wrinkles, and increases skin elasticity, firmness, roughness, and hydration. Evaluation of ascorbic acid and its derivatives, AA 2-phosphate e AAS 2-glucoside, on UVB-induced cytotoxicity in HaCaT human keratinocytes showed that, unlike its derivatives, ascorbic acid was unable to inhibit cytotoxicity.	Haftek et al., 2008; Raschke et al., 2004; Yasuda et al., 2004
Vitamin E*	One of the forms of vitamin E, α -tocopherol, is widely known for its antioxidant potential. The inhibitory role of α -tocopherol in the regulation of IL-8 and AP-1 production in human keratinocyte exposed to UVA was assessed and shown to inhibit significantly the activity of NADPH oxidase, which would be responsible for the activation of IL-8 and AP-1; α -tocopherol also inhibited malondialdehyde-thiobarbituric acid formation in cells exposed to UVA radiation.	Wu et al., 2008

<i>Vitis vinifera</i> shoot extract	V. vinifera shoot extract shows a higher in vitro antioxidant capability than vitamin C or E. An aquous V. vinifera L. tendril extract, applied in human keratinocytes (NCTC 2544) was able to increase the concentration of reduced glutathione and the activity of trans plasma membrane oxido reductase, in a time- and dose- dependent fashion, which demonstrates that the extract has a relevant antioxidant activity.	Cornacchione et al., 2007; Fraternale et al., 2011
Zeaxanthin and lutein*	Increased intake of lutein improved the health of the skin when supplemented orally or applied topically (zeaxanthin and lutein), as assessed on the basis of the following five physiological parameters: skin surface lipids, skin hydration, photoprotective activity, skin elasticity, and lipid peroxidation. Oral or topical administration improved such measurements significantly: oral administration resulted in better protection against changes in lipid peroxidation and in photoprotective activity following UV irradiation. Nevertheless, combined oral and topic administration provide a higher degree of protective effect of this combination against epidermal hyperproliferation and inflammation after UVB exposure in mice.	Evans and Johnson, 2010; González et al., 2003; Palombo et al., 2007

* Active ingredients with placebo/vehicle controlled studies in vivo in man. AKT (protein kinase B), AP-1 (activator protein 1), Bad (Bcl-2-associated death promoter), Bax (Bcl-2-associated X protein), Bcl-2 (B-cell lymphoma 2), c-fos (cellular oncogene fos), c-jun (cellular oncogene jun), CaMKs (calmodulin-dependent protein kinases), CGRP (calcitonin gene-related peptide), COX-2 (ciclooxigenase-2), ECG (epicatechin-3-gallate), EGCG (epigallocatechin-3-gallate), ERK (extracellular-signal-regulated kinases), FTGE (tannase-converted green tea extract), GSP (grape seed proanthocyanidins), IL (interleukin), iNOS (inducible nitric oxide synthase), JNK (c-Jun NH2-terminal kinase), MAPK (mitogen-activated protein kinases), MEK (mitogenactivated protein kinase kinase), MMP (matrix metalloproteinases), NF-κB (nuclear factor kappa B), Nrf2 (NF-E2-related factor 2), p21 (cyclin-dependent kinase inhibitor 1), p53 (protein 53), p65 (transcription factor p65), PARP-1 (Poly [ADP-ribose] polymerase 1), PCNA (proliferating cell nuclear antigen), POMx (polyphenol-rich pomegranate fruit extract), ROS (reactive oxygen species), SEK (stress-activated protein kinase/extracellular signal-regulated kinase), Ser (serine), SFB (sea buckthorn fruit blend), SOD (superoxide dismutase), TEWL

7.3. Aprovação do Comitê de Ética em Pesquisa

Comitê de Ética em Pesquisa. Rua Professor Pedro Viriato Parigot de Souza,5.300 Bloco Biotério, E1,1ºandar, Sala 103 Campo Comprido / CEP 81280-330 / Curitiba-PR cep@up.com.br

Curitiba - PR, 24 de outubro de 2011.

Carta de Aprovação Ética

O Comitê de Ética em Pesquisa da UP recebeu a emenda de 19 de outubro de 2011, referente ao protocolo 188/09 "Estudo dos Marcadores Biológicos Envolvidos no Envelhecimento Cutâneo Por Faixa Etária", elaborado pela professora Camila Miranda de Carvalho, não foram identificadas falhas éticas na emenda proposta, portanto essa comissão ética opina pela aprovação.

Atenciosamente,

Juliana Londero Vice-coordenadora do CEP - UP

7.4. Produtividade técnico-científica do aluno ao longo do curso de Doutorado

Resumo: The present invention relates to the use of plant extracts of Passiflora alata as an antiinflammatory agent in cosmetic and pharmaceutical compositions. The present invention further relates to a process for obtaining a plant extract of Passiflora alata comprising the steps of submitting the leaves of the Passiflora alata plants to an extraction with water to obtain an aqueous extract and submitting the aqueous extract thus obtained to at least one elution with an aqueous solution of ethanol in a specific column and later drying of said extract by spray-drying.

2) Título: Cosmetic composition comprising siliconed sapucainha ester and a cosmetic product comprising said composition

Inventores: Daisy de Fátima Scarparo de Sanctis, Débora Figueiredo Beda, Érica Dadario Brugnollo, Leandra Moraes Santos, Márcio Lorencini, Vanessa de Moura Sá Rocha

Código: US20130012577 / Abrangência: Estados Unidos / Data depósito: 06/01/2011 / Publicação: 10/01/2013

Depositante: Natura Cosméticos S.A.

Resumo: It describes an extraction process for obtaining a standardized extract of quercetin and 3-0-methylquercetin from inflorescences of macela-do-campo (Achyrocline satureioides) characterized by comprising of the following steps: A) grinding the inflorescences of Achyrocline satureioides to obtain a material of ground plant; B) submitting the ground plant to at least four sequential stages of hydro-alcoholic extraction at a temperature from 60°C to 80°C1 for 3 to 4 hours for each stage, in order to obtain 4 intermediary hydro-alcoholic extracts; C) combining the 4 intermediary hydro-alcoholic extracts; D) concentrating the intermediary hydro-alcoholic extracts mixture; in order to obtain up to a maximum of 20% of the initial mass of the intermediary hydroalcoholic extracts; E) drying the material obtained in (D). It also describes cosmetic, pharmaceutical and veterinary compositions containing the aforesaid extract of macela-do-campo, destined for the prevention and treatment of the damages arising from inflammatory, microbial and oxidation/lypoperoxidation reactions. The use and method of application of the aforesaid extract of macela are also described.

4) Título: Composição antienvelhecimento e formulação cosmética e/ou dermatológica contendo a mesma

Inventores: Carlos Eduardo de Oliveira Praes, Marcela Contador Baptista, Márcio Lorencini, Ruandro Victor Knapik

Código: PI 1005274-7 A2 / Abrangência: Brasil / Data depósito: 15/12/2010 / Publicação: publicada em 09/04/2013

Depositante: Botica Comercial Farmacêutica Ltda.

Resumo: Descreve-se a presente invenção como uma composição antienvelhecimento e formulação cosmética e/ou dermatológica contendo a mesma que, de acordo com as suas características gerais, propicia uma composição antienvelhecimento a partir de uma combinação de otimizada de ingredientes contendo sais minerais, com vistas a propiciar por meio da combinação otimizada destes ingredientes um aumento da produção de colágeno e, por conseguinte, a firmeza da pele, de modo a promover a minimização de rugas e linhas da pele e uma melhora efetiva do aspecto geral da pele, ambos obtidos diretamente pela ação balanceada destes ingredientes ricos em sais minerais.

5) **Título:** Composição farmacêutica para aplicação na pele

Inventores: Alessandro Afornali, Camila Miranda de Carvalho, Carlos Eduardo de Oliveira Praes, Fernanda Lourenço Angelucci, Márcio Lorencini, Priscila Fernanda Campos de Menezes, Ruandro Victor Knapik

Código: PI 1010479-8 / **Abrangência:** Brasil / **Data depósito:** 27/12/2010 / **Publicação:** notificação de depósito de pedido de patente em 15/05/2012

Depositante: Botica Comercial Farmacêutica Ltda.

Resumo: Conteúdo ainda não publicado pelo INPI.

6) Título: Composição cosmética e/ou dermatológica e formulação cosmética e/ou dermatológica contendo a referida composição

Inventores: Alessandro Afornali, Camila Miranda de Carvalho, Carlos Eduardo de Oliveira Praes, Márcio Lorencini, Priscila Fernanda Campos de Menezes

Código: PI 1005496-0 A2 / Abrangência: Brasil / Data depósito: 29/12/2010 / Publicação: publicada em 16/04/2013

Depositante: Botica Comercial Farmacêutica Ltda.

Resumo: A presente invenção refere-se a uma composição antienvelhecimento e formulação cosmética e/ou dermatológica contendo a referida composição. Esta mistura otimizada de ingredientes ativos é capaz de atuar positivamente sobre processos biológicos relacionados ao envelhecimento da pele, conferindo proteção e minimização dos sinais do relevo cutâneo. Este conjunto de características é obtido pela combinação de dois peptídeos e um polissacarídeo.

7) Título: Ingrediente cosmético e/ou dermatológico e formulação cosmética e/ou dermatológica contendo o mesmo

Inventores: Alessandro Afornali, Alexandre Roberto Silva, Bruna Bastos Swinka, Camila Miranda de Carvalho, Carlos Eduardo de Oliveira Praes, Luiza Fernanda Schier, Márcio Lorencini, Priscila Fernanda Campos de Menezes

Código: PI 1102721-5 A2 / Abrangência: Brasil / Data depósito: 10/06/2011 / Publicação: publicada em 16/07/2013

Depositante: Botica Comercial Farmacêutica Ltda.

Resumo: A presente invenção refere-se a um ingrediente e formulação cosmética e/ou dermatológica que apresenta ações de preservação da longevidade de células dérmicas (fibroblastos) e células-tronco adultas, de aumento do metabolismo celular, sustentação e adesão das células da pele e melhoria da função barreira, garantindo assim uma atividade antienvelhecimento diferenciada, com minimização dos sinais de envelhecimento da pele. Este conjunto de benefícios é proporcionado por uma fração obtida a partir de Malus sp.

8) Título: Composição nutritiva e formulação cosmética e/ou dermatológica contendo a mesma

Inventores: Alessandro Afornali, Alexandre Roberto Silva, Camila Miranda de Carvalho, Carlos Eduardo de Oliveira Praes, Márcio Lorencini, Priscila Fernanda Campos de Menezes, Ruandro Victor Knapik, Vanessa Vitoriano da Silva

Código: PI 1104880-8 / Data depósito: 27/10/2011 / Abrangência: Brasil / Publicação: notificação de depósito de pedido de patente em 14/08/2012

Depositante: Botica Comercial Farmacêutica Ltda.

Resumo: Conteúdo ainda não publicado pelo INPI.

9) Título: Ingrediente protetor da barreira cutânea e formulação cosmética e/ou dermatológica contendo o mesmo

Inventores: Alessandro Afornali, Bruna Bastos Swinka, Carla Abdo Brohem, Gustavo de Campos Diaemant, Israel Henrique Stokfisz Feferman, Marcela Contador Baptista, Márcio Lorencini, Tammy Proença Zagonel Nichele

Código: BR 10 2012 032898 4 / Data depósito: 21/12/2012 / Abrangência: Brasil / Publicação: notificação de depósito de pedido de patente em 11/06/2013

Depositante: Botica Comercial Farmacêutica Ltda.

Resumo: Conteúdo ainda não publicado pelo INPI.
